The simulated annealing method generates new trial solutions by adding a random vector to the current X vector. The elements of the random vector are set to *stepsize*<sub>*i*</sub>\**R<sub>i</sub>*, where *R<sub>i</sub>* is a random number in the interval (-1, 1). As the solution progresses, the *stepsize* is gradually decreased.

Bad trials, that is, those that change the function value in the wrong direction are accepted with a probability that depends on the simulated temperature. It is this aspect that allows simulated annealing to find a global minimum.

Function values are generated and accepted or rejected for some number of iterations at a given temperature, then the temperature is reduced. The probability of a bad iteration being accepted decreases with decreasing temperature. A too-fast cooling rate can freeze in a bad solution.

### Simulated Annealing Details

It is highly recommended that you use the XSA flag to specify *XLimitWave*. This wave sets bounds on the values of the elements of the X vector during the random search. The defaults may be adequate but are totally *ad hoc*. You are better off to specify bounds that make sense to the problem you are solving.

The values of *XLimitWave* in addition to bounding the search space also scale the X vector during computations of probabilities, temperatures, etc. Consequently, the X limits can affect the performance of the algorithm.

A large number of iterations is required to have a good probability of finding a reasonable solution.

It is recommended that you set the initial temperature to zero so that Optimize can estimate a good initial temperature. If you can't afford the 100 function evaluations required, you probably shouldn't be using simulated annealing.

Optimize uses an exponential cooling schedule in which  $T_{i+1} = \text{CoolingRate} * T_i$  (see the /TSA flag). *CoolingRate* must be in the range 0 to 1. A fast cooling rate (small value of *CoolingRate*) can cause simulated quenching; that is, a bad solution can be frozen in. Very slow cooling will result in slow convergence.

When simulated annealing is selected, the optimization is treated as multivariate even if your function has only a single X input. That is, the output variables and waves are the ones listed under multivariate functions.

### Variables and Waves for Output

The Optimize operation reports success or failure via the V\_flag variable. A nonzero value is an error code.

*Variables for a univariate function:*

V_flag	0:	Search for an extreme point was successful.
	57:	User abort.
	785:	Function returned NaN.
	786:	Unable to find bracketing values for an extreme point.

If you searched for a minimum:

V_minloc	X value at the minimum.
V_min	Function value (Y) at the minimum.

If you searched for a maximum:

V_maxloc	X value at the maximum.
V_max	Function value (Y) at the maximum.

For simulated annealing only:

V_SANumIncreases	Number of "bad" iterations accepted.
V_SANumReductions	Number of iterations resulting in a better solution.

*Variables for a multivariate function:*

V_flag	0:	Search for an extreme point was successful.
	57:	User abort.
	788:	Iteration limit was exceeded.
	789:	Maximum step size was exceeded in five consecutive iterations.
	790:	The number of points in the typical X size wave specified by /R does not match the number of X values specified by the /X flag
	791:	Gradient nearly zero and no iterations taken. This means the starting point is very nearly a critical point. It could be a solution, or it could be so close to a saddle point or a maximum (when searching for a minimum) that the gradient has no useful information. Try a slightly different starting point.
V_OptTermCode	Indicates why Optimize stopped. This may be useful information even if V_flag is zero. Values are:	
	1:	Gradient tolerance was satisfied.
	2:	Step size tolerance was satisfied.
	3:	No step was found that was better than the last iteration. This could be because the current step is a solution, or your function may be too nonlinear for Optimize to

## Override

---

solve, or your tolerances may be too large (or too small), or finite difference gradients are not sufficiently accurate for this problem.

- 4: Iteration limit was exceeded.
- 5: Maximum step size was exceeded in five consecutive iterations. This may mean that the maximum step size is too small, or that the function is unbounded in the search direction (that is, goes to -inf if you are searching for a minimum), or that the function approaches the solution asymptotically (function is bounded but doesn't have a well-defined extreme point).
- 6: Same as V\_flag = 791.

If you searched for a minimum:

V\_min            Function value (Y) at the minimum.

If you searched for a maximum:

V\_max            Function value (Y) at the maximum.

*Variables for all functions:*

V\_OptNumIters    Number of iterations taken before Optimize terminated.

V\_OptNumFunctionCalls    Number of times your function was called before Optimize terminated.

*Waves for a multivariate function:*

W\_extremum        Solution if you didn't use /X=<xWave>. Otherwise the solution is returned in your X wave.

W\_OptGradient    Estimated gradient of your function at the solution.

**See Also**

**Finding Minima and Maxima of Functions** on page III-281 for further details and examples.

**References**

The Optimize operation uses Brent's method for univariate functions. *Numerical Recipes* has an excellent discussion (see section 10.2) of this method (but we didn't use their code):

Press, William H., Saul A. Teukolsky, William T. Vetterling, and Brian P. Flannery, *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992.

For multivariate functions Optimize uses code based on Dennis and Schnabel. To truly understand what Optimize does, read their book:

Dennis, J. E., Jr., and Robert B. Schnabel, *Numerical Methods for Unconstrained Optimization and Nonlinear Methods*, 378 pp., Society for Industrial and Applied Mathematics, Philadelphia, 1996.

## Override

**Override constant *objectName* = newVal**

**Override strconstant *objectName* = newVal**

**Override Function *funcName*()**

The Override keyword redefines a constant, strconstant, or user function. The *objectName* or *funcName* must be the same as the name of the original object or function that is being redefined. The override must be defined before the target object appears in the compile sequence.

**See Also**

**Function Overrides** on page IV-66 and **Constants** on page IV-38 for further details.

## p

**p**

The p function returns the row number of the current row of the destination wave when used in a wave assignment statement. The row number is the same as the point number for a 1D wave.

**Details**

Outside of a wave assignment statement p acts like a normal variable. That is, you can assign a value to it and use it in an expression.

**See Also**

**Waveform Arithmetic and Assignments** on page II-80.

For other dimensions, the **q**, **r**, and **s** functions.

For scaled dimension indices, the **x**, **y**, **z**, and **t** functions.

**p2rect****p2rect(z)**

The p2rect function returns a complex value in rectangular coordinates derived from the complex value *z* which is assumed to be in polar coordinates (magnitude is stored in the real part and the angle, in radians, in the imaginary part of *z*).

**Examples**

Assume waveIn and waveOut are complex, then:

```
waveOut = p2rect(waveIn)
```

sets each point of waveOut to the rectangular coordinates based on the magnitude in the real part and the angle (in radians) in the imaginary part of the points in waveIn.

You may get unexpected results if the number of points in waveIn differs from the number of points in waveOut.

**See Also**

The functions **cmplx**, **conj**, **imag**, **r2polar**, and **real**.

**PadString****PadString(str, finalLength, padValue)**

The PadString function returns a string identical to *str* except that it has been extended to a total length of *finalLength* using bytes of *padValue*. Use zero to create a C-language style string or use 0x20 to pad with spaces (FORTRAN style). This is useful when reading or writing binary files using **FBinRead** and **FBinWrite**.

**Panel****Panel**

Panel is a procedure subtype keyword that identifies a macro as being a control panel recreation macro. It is automatically used when Igor creates a window recreation macro for a control panel. See **Procedure Subtypes** on page IV-149 and **Saving a Window as a Recreation Macro** on page II-51 for details.

**ParamIsDefault****ParamIsDefault(pName)**

The ParamIsDefault function determines if an optional user function parameter *pName* was specified during the function call. It returns 1 when *pName* is default (not specified) or it returns 0 when it was specified.

**Details**

ParamIsDefault works only in the body of a user function and only with optional parameters. The variable *pName* must be valid at compile time; you can not defer lookup to runtime with \$.

**See Also**

**Optional Parameters** on page IV-29 and **Using Optional Parameters** on page IV-46.

**ParseFilePath****ParseFilePath(mode, pathInStr, separatorStr, whichEnd, whichElement)**

The ParseFilePath function provides the ability to manipulate file paths and to extract sections of file paths.

**Parameters**

Several of the modes refer to elements of the file path. In these modes, *whichEnd* is 0 to select an element relative to the beginning of *pathInStr*, 1 to select an element relative to the end. *whichElement* is zero-based.

*pathInStr* is the input path, assumed to either a full path, a partial path (starts with the separator specified by *separatorStr*) or a simple file or folder name (contains no separators).

## ParseFilePath

---

<i>mode</i>	Information Returned
0	Element specified by <i>whichEnd</i> and <i>whichElement</i> .
1	Entire <i>pathInStr</i> , up to but not including the element specified by <i>whichEnd</i> and <i>whichElement</i> .
2	Entire <i>pathInStr</i> with a trailing separator added if it is not already there. This is useful when you have a path to a folder and want to tack on a file name.
3	Last element of <i>pathInStr</i> with the extension, if any, removed. The extension is anything after the last dot in <i>pathInStr</i> .
4	Extension in <i>pathInStr</i> or "" if there is no extension. The extension is anything after the last dot in <i>pathInStr</i> .
5	Entire <i>pathInStr</i> but converts it to a format determined by <i>separatorStr</i> . <i>separatorStr</i> = ":" Converts the path to Macintosh style if it is Windows style. Does nothing to a Macintosh path. <i>separatorStr</i> = "\\\" Converts the path to Windows style if it is Macintosh style. Does nothing to a Windows path. <i>separatorStr</i> = "*" Converts the path to the native style of the operating system Igor is running on. Does nothing to a native path.
6	UNC volume name ("\\Server\Share") if <i>pathIn</i> is a UNC path or "" if it is not.
7	UNC server name ("Server" from "\\Server\Share") if <i>pathIn</i> is a UNC path or "" if it is not.
8	UNC share name ("Share" from "\\Server\Share") if <i>pathIn</i> is a UNC path or "" if it is not.

---

*separatorStr* is ":" if *pathInStr* is a Macintosh path or "\\\" if *pathInStr* is a Windows path. See **Path Separators** on page III-382 for details about Macintosh versus Windows paths.

*whichEnd* is 0 to extract an element from the beginning of *pathInStr* or 1 to extract if from the end. *whichEnd* is used only if *mode* is 0 or 1. For other modes, pass 0.

*whichElement* is a zero-based index to the element that you want to extract. *whichElement* is used only if *mode* is 0 or 1. For other modes, pass 0.

### Details

When dealing with Windows paths, you need to be aware that Igor treats the backslash character as an escape character. When you want to put a backslash in a literal string, you need to use two backslashes. See see **Escape Characters in Strings** on page IV-13 and **Path Separators** on page III-382 for details.

On Windows two types of file paths are used: drive-letter paths and UNC ("Universal Naming Convention") paths. For example:

```
// This is a drive-letter path.  
C:\Program Files\WaveMetrics\Igor Pro Folder\Igor.exe  
  
// This is a UNC path.  
\\BigServer\SharedApps\Igor Pro Folder\Igor.exe
```

In this example, `ParseFilePath` considers the volume name to be `C:` in the first case and `\\BigServer\SharedApps` in the second. The volume name is treated as one element by `ParseFilePath`, except for modes 7 and 8 which permit you to extract the components of the UNC volume name.

Except for the leading backslashes in a UNC path, `ParseFilePath` modes 0 and 1 internally strip any leading or trailing separator (as defined by the *separatorStr* parameter) from *pathInStr* before it starts parsing. So if you pass `":Igor Pro Folder:WaveMetrics Procedures:"`, it is the same as if you had passed `"Igor Pro Folder:WaveMetrics Procedures"`.

If there is no element corresponding to *whichElement* and *mode* is 0, `ParseFilePath` returns "".

If there is no element corresponding to *whichElement* and *mode* is 1, `ParseFilePath` returns the entire *pathInStr*.

### Examples

```
String pathIn, pathOut
```

```

// Full path
pathIn= "hd:Igor Pro Folder:WaveMetrics Procedures:Waves:Wave Lists.ipf"
// Extract first element.
Print ParseFilePath(0, pathIn, ":", 0, 0)          // Prints "hd"
// Extract second element.
Print ParseFilePath(0, pathIn, ":", 0, 1)         // Prints "Igor Pro Folder"
// Extract last element.
Print ParseFilePath(0, pathIn, ":", 1, 0)         // Prints "Wave Lists.ipf"
// Extract next to last element.
Print ParseFilePath(0, pathIn, ":", 1, 1)         // Prints "Waves"
// Get path to folder containing the file.
// Prints "hd:Igor Pro Folder:WaveMetrics Procedures:Waves:"
Print ParseFilePath(1, pathIn, ":", 1, 0)
// Extract the file name without extension.
Print ParseFilePath(3, pathIn, ":", 0, 0)         // Prints "Wave Lists"
// Extract the extension.
Print ParseFilePath(4, pathIn, ":", 0, 0)         // Prints ".ipf"
// Make sure the given path ends with a colon and concatenate file name.
String path = <routine that returns a Macintosh-style path to a folder>
path = ParseFilePath(2, path, ":", 0, 0)
path += "AFile.txt"

```

## ParseOperationTemplate

**ParseOperationTemplate** [*flags*] *cmdTemplate*

The ParseOperationTemplate operation helps XOP programmers and WaveMetrics programmers write code to implement Igor operations. If you are not an XOP programmer nor a WaveMetrics programmer, it will be of no interest.

ParseOperationTemplate is used to generate starter code for programmers who are creating Igor operations. The starter code is copied to the Clipboard, overwriting any previous Clipboard contents.

**Flags**

- /C=c*     If *c* is nonzero, ParseOperationTemplate stores code for your ExecuteOperation and RegisterOperation functions in the Clipboard.  
Use */C=1* for simple code generation. Use */C=2* for more extensive code generation.
- /S=s*     Stores a definition of your runtime parameter structure in the Clipboard if *s* is nonzero.  
This parameter affects code generation if you use mnemonic names in your template. With */S=1*, your structure field names will be the same as the specified mnemonic names. This is fine if your mnemonic names are unique. However, if two or more of your parameters use the same mnemonic name, use */S=2*. In this case, ParseOperationTemplate will create unique field names by concatenating flag or keyword text and the specified mnemonic names.
- /T*       Stores a comment listing your command template in the Clipboard.
- /TS*      Identifies a ThreadSafe operation by adding an extra field to the runtime parameter structure. This is only of use to WaveMetrics programmers.

**Parameters**

*cmdTemplate* is the template that describes the syntax for your operation. See the *Igor XOP Toolkit Reference Manual* for details.

**Details**

ParseOperationTemplate parses your command template, generating structures that embody the syntax of your operation. If the */C*, */S* or */T* flags is used, it then uses these structures to generate code that can serve as a starting point for implementing your operation. The starter code is stored in the Clipboard.

For most uses, the recommended flags are */T/S=1/C=2*.

ParseOperationTemplate sets the following output variable, but only when called from a function or macro:

*v\_flag*    0:       *cmdTemplate* was successfully parsed.

## PathInfo

---

-1: *cmdTemplate* was not successfully parsed.

If *V\_flag* is nonzero, this indicates that your *cmdTemplate* syntax is incorrect. See the *Igor XOP Toolkit Reference Manual* for details.

### Examples

```
Function Test()  
  String cmdTemplate  
  cmdTemplate="MyTest /A={number,string} /B=wave key1={name[,wave,name,string[2]]}"  
  TestOperationParser/T/S=1/C=2 cmdTemplate  
  Print V_flag, S_value  
End
```

### See Also

**Igor Extensions** on page III-407.

## PathInfo

**PathInfo** [/S] *pathName*

The PathInfo operation stores information about the named symbolic path in the following variables:

*V\_flag*: 0 if path does not exist, 1 if it does exist.

*S\_path*: The full path (e.g., "hd:This:That").

The path returned is a colon-separated path which can be used on Macintosh or Windows. See **Path Separators** on page III-382 for details.

### Flags

/S Presets the next otherwise undirected open or save file dialog to the given disk folder.

### Examples

The following lines perform equivalent actions:

```
PathInfo/S myPath;Open refNum  
Open/P=myPath refNum
```

## PathList

**PathList**(*matchStr*, *separatorStr*, *optionsStr*)

The PathList function returns a string containing a list of symbolic paths selected based on the *matchStr* parameter.

### Details

For a path name to appear in the output string, it must match *matchStr*. The first character of *separatorStr* is appended to each path name as the output string is generated.

PathList works like the WaveList function, except that the *optionsStr* parameter is reserved for future use. Pass "" for it.

### Examples

When a new experiment is created there is only one path:

```
Print PathList("*",";","")
```

Prints the following in the history area:

```
Igor;
```

### See Also

The **WaveList** function for an explanation of the *matchStr* and *separatorStr* parameters and for examples. See also **Symbolic Paths** on page II-30 for an explanation of symbolic paths.

## PauseForUser

**PauseForUser** *mainWindowName* [, *targetWindowName*]

The PauseForUser operation pauses procedure execution until the specified window, *mainWindowName*, is killed. Until then, only mouse and keyboard activity directed toward either *mainWindowName* or *targetWindowName* will be allowed. This affects graph, table, and panel windows only.

While waiting for user action, `PauseForUser` disables double-clicks and any contextual menus that can lead to dialogs to prevent changes on the command line. It also disables killing windows by clicking the close icon in the title bar unless the window was originally created with the `/K=1` flag.

#### See Also

`Pause For User` on page IV-108 for examples and further discussion.

## PauseUpdate

### PauseUpdate

The `PauseUpdate` operation delays the updating of graphs and tables until you invoke a corresponding `ResumeUpdate` command.

#### Details

`PauseUpdate` is useful in a macro that changes a number of things relating to the appearance of a graph. It prevents the graph from being updated after each change. Its effect ends when the macro in which it occurs ends. It also affects updating of tables.

This operation is not allowed from the command line. It is allowed but has no effect in user-defined functions. During execution of a user-defined function, windows update only when you explicitly call the `DoUpdate` operation.

#### See Also

The `DelayUpdate`, `DoUpdate`, `ResumeUpdate`, and `Silent` operations.

## PCA

### PCA [*flags*][*wave0*, *wave1*,... *wave99*]

The PCA operation performs principal component analysis. Input data can be in the form of a list of 1D waves, a single 2D wave, or a string containing a list of 1D waves. The operation can produce multiple output waves depending on the specified flags.

#### Flags

<code>/ALL</code>	Shortcut for the combination of commonly used flags: <code>/CVAR</code> , <code>/SL</code> , <code>/NF</code> , <code>/IND</code> , <code>/IE</code> , and <code>/RMS</code> .
<code>/COV</code>	Calculates the input wave(s) covariance matrix, which as the input for the remainder of the analysis. The covariance matrix is computed by first creating a matrix copying each input 1D wave into sequential columns and then multiplying that matrix by its transpose.
<code>/CVAR</code>	Computes the cumulative percent variance defined as $100 * \text{sum of first } m \text{ eigen values} / \text{sum of all eigen values}$ . The results are stored in the wave <code>W_CumulativeVAR</code> in the current data folder. See also <code>/VAR</code> .
<code>/IE</code>	Computes the imbedded error. Returns errors in the wave <code>W_IE</code> in the current data folder. The wave is scaled using <code>SetScale/P x 1,1,"", W_IE</code> . The imbedded error is a function of the number of factors, the number of rows and columns and the sum of the eigen vectors not included in the significant factors. The behavior of <code>IE</code> determines the number of significant factors.
<code>/IND</code>	Computes the factor indicator function. Note that if you specify <code>/IND</code> the residual standard deviation will also be calculated. Returns results in the wave <code>W_IND</code> in the current data folder. The wave is scaled using <code>SetScale/P x 1,1,"", W_IND</code> .
<code>/LEIV</code>	Limits eigen values so that the SVD calculation does not require too much memory. The limit is set to the minimum of the number of rows or columns of the input.
<code>/NF</code>	Finds the number of significant factors and stores it in the variable <code>V_npnts</code> . You must use <code>/IND</code> in order to compute the significant factors.
<code>/O</code>	Overwrites input waves.
<code>/Q</code>	Suppresses printing of factors in the history area.
<code>/RSD[=<i>rsdMode</i>]</code>	Computes the Residual Standard Deviation (RSD) and returns the RSD in the wave <code>W_RSD</code> in the current data folder. The first element in <code>W_RSD</code> is NaN and all remaining wave elements correspond to the number of significant factors. <code>rsdMode =0:</code> Covariance about the origin. <code>rsdMode =1:</code> Correlation about the origin.

---

/RMS	Computes the RMS error. Returns results in the wave W_RMS in the current data folder. The wave is scaled using $\text{SetScale}/P \times 1, 1, "", W\_RMS$ .
/SCMT	Saves C matrix after the singular value decomposition (SVD) in the wave M_C in the current data folder.
/SCR	Converts the individual wave input into standard scores. Does not work when the input is a single 2D wave. It is an error to convert to standard scores when one or more entries in the waves are NaN or INF. If you use this feature make sure to use the appropriate form of the RSD calculation.
/SDM	Saves a copy of the data matrix at the end of the calculation. This is useful if your input consists of individual waves or if you want to save the computed standard scores. If the input is a 2D matrix, you will get a copy of the input matrix in the wave M_D.
/SEVC	Saves the eigen value vector in the wave W_Eigen, which are the raw eigen values generated by the SVD, in the current data folder. Normally, if the SVD was applied to a raw data matrix, i.e., not covariance or correlation matrix, you must square each element of the wave to obtain the PCA eigen values. Note that this wave has default wave scaling.
/SL	Computes percent significance level and stores it in the wave W_PSL in the current data folder.
/SQEV	Does not square SVD eigen values. If you specify /COV there is no need to use this flag. Use only if your input is already a covariance matrix. In this case the results of the SVD are the eigen values not their square roots.
/SRMT	Saves R matrix after the SVD in the wave M_R in the current data folder.
/U	Leaves the input waves unchanged only when the input is a 2D wave. Note that covariance calculations will not be made even if the appropriate flag is used.
/VAR	Computes the variance associated with each eigen value. The variance is defined as the ratio of the eigen value to the sum of all eigen values. The results are stored in the wave W_VAR in the current data folder. See also /CVAR above.
/WSTR= <i>waveListStr</i>	String containing a list of names for all input waves.
/Z	No error reporting.

### Details

The input is either via /WSTR=*waveListStr* or a list of up to 100 1D waves or a single 2D wave following the last flag.

*waveListStr* is string containing a semicolon-separated list of 1D waves to be used for the data matrix. *waveListStr* can include any legal path to a wave. Liberal names can be quoted or not quoted. It is assumed that all waves are of the same numerical type (either single or double precision) and that all waves have the same number of points.

Regardless of the inputs, the operation expects that the number of rows in the resulting matrix is greater than or equal to the number of columns.

The operation starts by creating the data matrix from the input wave(s). If you provide a list of 1D waves they become the columns of the data matrix. You can choose to use the covariance matrix (/COV) as the data matrix and you can also choose to normalize each column of the data matrix to convert it into standard scores. This involves computing the average and standard deviation of each column and then setting the new values to be:

$$\text{newValue} = \frac{\text{oldValue} - \text{colAverage}}{\text{colStdv}}.$$

You can pre-process the input data using **MatrixOP** with the SubtractMean, NormalizeRows, and NormalizeCols functions.

After creating the data matrix the operation computes the singular value decomposition (SVD) of the data matrix. Results of the SVD can be saved or processed further. Save the C and R matrices using /SCMT and /SRMT. These are related to the input data matrix through:  $D = R \cdot C$ .

The remainder of the operation lets you compute various statistical quantities defined by Malinowski (see References). Use the flags to determine which ones are computed.

The operation generates a number of output waves. All waves are stored in the current data folder.

You can save the input matrix D in the wave M\_D, the optional SVD results are stored in the waves M\_C that contains the column matrix C, M\_R that contains the row matrix R, and W\_Eigen that contains the eigen values of the data matrix. Note that these can be the eigen values or the square of the eigen values depending on the input matrix being a covariance matrix or not (see /SQEV).

The optional 1D output waves (W\_RSD, W\_RMS, W\_IE, W\_IND, W\_PSL) are saved with wave scaling to make it easier to display the wave as a function of the number of factors.

## pcsr

### **pcsr(cursorName [, graphNameStr])**

The pcsr function returns the point number of the point which the specified cursor (A through J) is on in the top (or named) graph. When used with cursors on images or waterfall plots, pcsr returns the row number, and when used with a free cursor, it returns the relative X coordinate.

### Parameters

*cursorName* identifies the cursor, which can be cursor A through J.

*graphNameStr* specifies the graph window or subwindow.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

### Details

The pcsr result is not affected by any X axis.

### See Also

The **Cursor** operation and the **CsrInfo**, **hcsr**, **qcsr**, **vcscr**, **xcscr**, and **zcscr** functions.

## Pi

### **Pi**

The Pi function returns  $\pi$  (3.141592...).

## PICTInfo

### **PICTInfo(pictNameStr)**

The PICTInfo function returns a string containing a semicolon-separated list of information about the named picture. If the named picture does not exist, then "" is returned. Valid picture names can be found in the Pictures dialog.

### Details

The string contains six pieces of information, each prefaced by a keyword and colon and terminated with a semicolon.

Keyword	Information Following Keyword
TYPE	One of: "PICT", "PNG", "JPEG", "Enhanced metafile", "Windows metafile", "DIB", "Windows bitmap", or "Unknown type".
BYTES	Amount of memory used by the picture.
WIDTH	Width of the picture in pixels.
HEIGHT	Height of the picture in pixels.
PHYSWIDTH	Physical width of the picture in points.
PHYSHEIGHT	Physical height of the picture in points.

## PICTList

---

### Examples

```
print PictInfo("PICT_0")
```

will print the following in the history area:

```
TYPE:PICT;BYTES:55734;WIDTH:468;HEIGHT:340;PHYSWIDTH:468;PHYSHEIGHT:340;
```

### See Also

The **ImageLoad** operation for loading PICT and other image file types into waves, and the **PICTList** function. The **StringFromList** operation for parsing the information string.

See **Pictures** on page III-405 and **Pictures Dialog** on page III-406 for general information on picture handling.

## PICTList

### **PICTList**(*matchStr*, *separatorStr*, *optionsStr*)

The **PICTList** function returns a string containing a list of pictures based on *matchStr* and *optionsStr* parameters. See **Details** for information on listing pictures in graphs, panels, layouts, and the picture gallery.

### Details

For a picture name to appear in the output string, it must match *matchStr* and also must fit the requirements of *optionsStr*. The first character of *separatorStr* is appended to each picture name as the output string is generated.

The name of each picture is compared to *matchStr*, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

```
"*"           Matches all picture names.
"xyz"         Matches picture name xyz only.
"*xyz"        Matches picture names which end with xyz.
"xyz*"        Matches picture names which begin with xyz.
"*xyz*"       Matches picture names which contain xyz.
"abc*xyz"     Matches picture names which begin with abc and end with xyz.
```

*matchStr* may begin with the ! character to return windows that do not match the rest of *matchStr*. For example:

```
"!*xyz"       Matches picture names which do not end with xyz.
```

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of *matchStr*.

*optionsStr* is used to further qualify the picture.

Use " " accept all pictures in the Pictures Dialog that are permitted by *matchStr*.

Use the WIN: keyword to limit the pictures to the named or target window:

```
"WIN:"         Match all pictures displayed in the top graph, panel, or layout.
"WIN:windowName" Match all pictures displayed in the named graph, panel, or layout window.
```

### Examples

```
PICTList("*", ";", "")           Returns a list of all pictures in the Pictures Dialog.
PICTList("*", ";", "WIN:")       Returns a list of all pictures displayed in the top panel, graph, or
                                  layout.
PICTList("*_bkg", ";", "WIN:Layout0") Returns a list of pictures whose names end in "_bkg" and which
                                  are displayed in Layout0.
```

### See Also

The **ImageLoad** operation for loading PICT and other image file types into waves, and the **PICTInfo** function. Also the **StringFromList** function for retrieving items from lists.

See **Pictures** on page III-405 and **Pictures Dialog** on page III-406 for general information on picture handling.

## Picture

### **Picture** *pictureName*

The **Picture** keyword introduces an ASCII code picture definition of binary image data.

#### **See Also**

**Proc Pictures** on page IV-44 for further information.

## PixelFromAxisVal

### **PixelFromAxisVal**(*graphNameStr*, *axNameStr*, *val*)

The **PixelFromAxisVal** function returns the local graph pixel coordinate corresponding to the axis value in the graph window or subwindow.

#### **Parameters**

*graphNameStr* can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

If the specified axis is not found and if the name is "left" or "bottom" then the first vertical or horizontal axis will be used.

#### **See Also**

The **AxisValFromPixel** and **TraceFromPixel** functions.

## PlayMovie

### **PlayMovie** [*flags*] [*as fileNameStr*]

The **PlayMovie** operation opens a QuickTime movie file into a window and plays it.

#### **Parameters**

The file to be opened is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

#### **Flags**

<i>/I</i>	Coordinates are in inches.
<i>/M</i>	Coordinates are in centimeters.
<i>/P=pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
<i>/W=(left,top,right,bottom)</i>	Sets the initial coordinates of the movie window (in points unless <i>/I</i> or <i>/M</i> are used before <i>/W</i> ).
<i>/Z</i>	No error reporting; an error is indicated by nonzero value of the variable <i>V_flag</i> . If the user clicks the cancel button in the Open File dialog, <i>V_flag</i> is set to -1.

#### **Details**

Coordinates are the initial coordinates of the movie window in points unless */I* or */M* are used before */W*. Only the *top* and *left* coordinates are used. The window has the standard width and height for movies.

If either the path or *fileNameStr* is omitted then **PlayMovie** will bring up a dialog to let you find a movie file. If both are present, **PlayMovie** opens the file automatically.

If you use */P=pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-30 for details.

Any movie file can be played, not just movies made by Igor. There is no limit on the number of movie windows opened for playing.

Movie windows are considered transient and are not restored when an experiment is reopened.

## PlayMovieAction

---

### See Also

The **PlayMovieAction** operation.

## PlayMovieAction

**PlayMovieAction** [*/Z*] *keyword* [=value][, *keyword* [=value]]

PlayMovieAction operates on the top movie window (opened via **PlayMovie**).

If the */Z* flag is present, errors are not fatal. *V\_flag* is set to error return regardless.

### Parameters

extract	Extracts current frame into an 8-bit RGB image wave named <i>M_MovieFrame</i> . (Can be combined with <i>frame=f</i> .)
extract= <i>e</i>	Extracts <i>e</i> frames into a single multiframe wave, <i>M_MovieChunk</i> . This wave will have 3 planes for RGB and will have <i>e</i> chunks.
frame= <i>f</i>	Moves to specified movie frame (and stops movie).
getID	Returns top movie ID number in <i>V_Value</i> . Do not use in same call with <i>getTime</i> .
getTime	Reads current movie time into variable <i>V_value</i> (in seconds).
gotoBeginning	Goes to beginning of movie.
gotoEnd	Goes to end of movie.
kill	Kills movie window.
setFrontMovie= <i>id</i>	Sets movie with given <i>id</i> as top window. Error if no such window (use <i>/Z</i> to suppress errors). Do not use in same call with <i>getID</i> .
start	Starts movie playing.
step= <i>s</i>	Moves by <i>s</i> frames into movie (0 is same as 1, negative values move backwards).
stop	Stops movie.

### Flags

*/Z* No error reporting; an error is indicated by nonzero value of the variable *V\_flag*.

### Details

Operations are performed in the following order: *kill*, *stop*, *gotoBeginning*, *gotoEnd*, *frame*, *step*, *getTime*, *extract*, *start*. *kill* overrides all other parameters.

If you want to extract a grayscale image, you can convert the RGB image into grayscale using the **ImageTransform** command as follows:

```
PlayMovieAction extract
ImageTransform rgb2gray M_MovieFrame
NewImage M_RGB2Gray
```

### Examples

How to determine the number of frames in a simple movie:

```
PlayMovie
PlayMovieAction stop, gotoEnd, getTime
Variable tend= V_value
PlayMovieAction step=-1, getTime
Print "frames= ", tend/(tend-V_value)
PlayMovieAction kill
```

### See Also

The **PlayMovie** operation.

## PlaySnd

**PlaySnd** [*flags*] *fileNameStr*

Available only on the Macintosh.

The **PlaySnd** operation plays a sound from the file's data fork, or from an 'snd' resource.

### Parameters

The file containing the sound is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path

relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

### Flags

<i>/I=resourceIndex</i>	Specifies the 'snd ' resource to load by resource index, starting from 1.
<i>/M=promptStr</i>	Specifies a prompt if PlaySnd needs to put up a dialog to find the file.
<i>/N=resNameStr</i>	Specifies the resource to load by resource name.
<i>/P=pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
<i>/Q</i>	Quiet: suppresses the insertion of 'snd ' info into the history area.
<i>/R=resourceID</i>	Specifies the 'snd ' resource to load by resource ID.
<i>/Z</i>	Does not play the sound, just checks for its existence.

### Details

If none of */I*, */N* or */R* are specified, PlaySnd tries to play a sound stored in the data fork of the file. If the file dialog is used, only files of type 'sfil' are shown.

If any of */I*, */N* or */R* are specified, PlaySnd tries to play a sound from an 'snd ' resource. Most programs store sounds in 'snd ' resources. If the file dialog is used, files of all types are shown.

If */P=pathName* is omitted, then *fileNameStr* can take on three special values:

"Clipboard"	Loads data from Clipboard.
"System"	Loads data from System file.
"Igor" (not "Igor Pro")	Loads data from Igor Pro application.

If you specify */P=pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\Folder1\\". See **Symbolic Paths** on page II-30 for details.

There are no sounds in the Igor Pro application file.

If the file is not fully specified and *fileNameStr* is not one of these special values, then PlaySnd presents a dialog from which you can select a file. "Fully specified" means that Igor can determine the name of the file (from the *fileNameStr* parameter) and the folder containing the file (from the */P=pathName* flag or from the *fileNameStr* parameter).

PlaySnd sets the variable *V\_flag* to 1 if the sound exists and fits in available memory or to 0 otherwise.

If the sound exists, PlaySnd also sets the string variable *S\_Info* to:

```
"SOURCE:sourceName;RESOURCENAME:resourceName;RESOURCEID:resourceID"
```

If the sound is not a resource then *resourceName* is "" and *resourceID* is 0. *sourceName* will be the name of the file that was loaded or "Clipboard", "System" or "Igor".

### Examples

```
PlaySnd/I=1/P=mySnds/Z "Wild Eep"
If (V_flag)           // Any 'snd ' in the "Wild Eep" file?
    Print S_info      // Yes, print resource number, etc.
Endif
```

This prints the following into the history area:

```
SOURCE:resource fork;RESOURCENAME:Wild Eep;RESOURCEID:8;
```

## PlaySound

**PlaySound** [*/A[=a]* */C*] *soundWaveName*

**PlaySound** */A[=a]* {*soundWaveName1*, *soundWaveName2* [, *soundWaveNameN...*]}

The PlaySound operation plays the audio samples in the named wave. The various sound output parameters — number of samples, sample rate, number of channels, and number of bits of resolution — are determined by the corresponding parameters of the wave.

## pnt2x

---

### Flags

`/A[=a]` Plays sounds asynchronously so that sounds will continue to play after the command itself has executed.

- `/A=0`: Same as no `/A` flag.
- `/A=1`: Plays sounds asynchronously; same as `/A`.
- `/A=2`: Stop playing any current sound before starting this one
- `/A=3`: Return with user abort error if output buffers are full (rather than waiting.) Use `GetRTError(1)` to detect and clear the error condition.

`/C` Samples audio at 16 bits. Has no effect with 8-bit waves.

### Details

The wave's time per point, as determined by its X scaling, which must be between  $2 \times 10^{-4}$  and  $1.5625 \times 10^{-5}$  or sampling rates of 5000 to 64000 Hertz.

For waves that are 8-bit integers or 32-bit floats, the audio samples will be converted to 8 bits and should range between -128 and +127.

If the wave is 16-bit integers or if the `/C` (for CD) flag is used, the samples will be converted to 16 bits and should range between -32768 and +32767. If an 8-bit wave is used then the `/C` flag is ignored.

With the `/A` flag, the sound plays asynchronously (i.e., the command returns before the sound is finished). If another command is issued before the sound is finished then the new command will wait until the last sound finishes. A `PlaySound` without the `/A` flag can play on top of the current sound. The transition between sounds should be seamless on Macintosh but may be slightly delayed on Windows.

It is OK to kill a sound wave immediately after `PlaySound` returns even if the `/A` flag is used.

To play a stereo sound, provide a 2 column wave with the left channel in column 0. Actually, the software will attempt to play as many channels as there are columns in the wave. You can also use multiple 1D waves with the `/A` flag. To use this method, enclose the list of 1D waves in braces

**Note:** The `SoundInput` operations provide matching sound recording capabilities. See the `SoundInStatus` operation.

### Examples

Under Windows, support for sound is somewhat idiosyncratic so these sound examples may not work correctly with your particular hardware configuration.

```
Make/B/O/N=1000 sineSound // 8 bit samples
SetScale/P x,0,1e-4,sineSound // Set sample rate to 10Khz
sineSound= 100*sin(2*Pi*1000*x) // Create 1Khz sinewave tone
PlaySound sineSound
```

The following example will create a rising pitch in the left channel and a falling pitch in the right channel:

```
Make/W/O/N=(20000,2) stereoSineSound // 16 bit data
SetScale/P x,0,1e-4, stereoSineSound // Set sample rate to 10Khz
stereoSineSound= 20000*sin(2*Pi*(1000 + (1-2*q)*150*x)*x)
PlaySound/A stereoSineSound // 16 bit, asynchronous
```

Multichannel sounds as in the previous example but from multiple 1D waves:

```
Make/W/O/N=20000 stereoSineSoundL, stereoSineSoundR // 16 bit data
SetScale/P x,0,1e-4, stereoSineSoundL, stereoSineSoundR // Set sample rate to 10Khz
stereoSineSoundL= 20000*sin(2*Pi*(1000 + 150*x)*x) // rising pitch in left
stereoSineSoundR= 20000*sin(2*Pi*(1000 - 150*x)*x) // falling in right
PlaySound/A {stereoSineSoundL, stereoSineSoundR} // two 1D waves
```

## pnt2x

### **pnt2x(waveName, pointNum)**

The `pnt2x` function returns the X value of the named wave at the point `pointNum`. The point number is truncated to an integer before use.

### Details

The result is derived from the wave's X scaling, not any X axis of a graph it may be displayed in. If you would like to convert a fractional point number to an X value you can use:

```
leftx(waveName)+deltax(waveName)*pointNum.
```

There is no equivalent function for multidimensional waves. To calculate this information for other dimensions, use this expression:

`DimOffset(waveName, dim) + ScaledDimPos*DimDelta(waveName, dim)`

This expression calculates the scaled position of an element in the dimension *dim* (x, y, z, or t). *ScaledDimPos* is the element number in that dimension (p, q, r, or s). *dim* is 0 for rows, 1 for columns, 2 for layers or 3 for chunks. Setting *dim* = 0 is equivalent to using `pnt2x`. You may want to use **round**, **ceil**, or **floor** to truncate the result to an integer.

**See Also**

The functions **DimDelta** and **DimOffset**.

**Waveform Model of Data** on page II-64 and **Changing Dimension and Data Scaling** on page II-70 for an explanation of waves and dimension scaling.

## poissonNoise

**poissonNoise(num)**

The `poissonNoise` function returns a pseudo-random value from the Poisson distribution whose probability distribution function is

$$f(x, \lambda) = \frac{e^{-\lambda} \lambda^x}{x!}, \quad \lambda > 0, \quad x = 0, 1, 2, \dots$$

with mean and variance equal to *numI* (=  $\lambda$ ).

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **SetRandomSeed**.

## poly

**poly(coefsWaveName, x1)**

The `poly` function returns the value of a polynomial function at  $x = x1$ .

*coefsWaveName* is a wave that contains the polynomial coefficients. The number of points in the wave determines the number of terms in the polynomial.

**Examples**

To fill `wave0` with 100 points containing the polynomial  $1 + 2*x + 3*x^2 + 4*x^3$  evaluated over the range from  $x = -1$  to  $x = 1$  (and graph it):

```
Make coefs = {1, 2, 3, 4} // f(x) = 1 + 2*x + 3*x^2 + 4*x^3
Make/N=100/O wave0; SetScale/I x, -1, 1, wave0; Display wave0
wave0 = poly(coefs, x)
```

## poly2D

**poly2D(coefsWaveName, x1, y1)**

The `poly2D` function returns the value of a 2D polynomial function at  $x = x1, y = y1$ .

*coefsWaveName* is a wave that contains the polynomial coefficients. The number of points in the wave determines the number of terms in the polynomial and therefore the polynomial degree.

**Details**

The coefficients wave contains polynomial coefficients for low degree terms first. All coefficients for terms of a given degree must be present, even if they are zero. Among coefficients for a given degree, those for terms having higher powers of X are first. Thus, `poly2D` returns, for a coefficient wave *cw*:

$$f(x,y) = cw[0] + cw[1]*x + cw[2]*y + cw[3]*x^2 + cw[4]*x*y + cw[5]*y^2 + \dots$$

A 2D polynomial of degree N has  $(N+1)(N+2)/2$  terms.

**Examples**

To fill `wave0` with 400 points (20 by 20) containing the polynomial  $1 + 2*x + 2.5*y + 3*x^2 + 3.5*xy + 4*y^2$  evaluated over the range  $x = (-1, 1)$  and  $y = (-1, 1)$  and make a contour plot of it:

## PolygonArea

---

```
Make/O coefs = {1, 2, 2.5, 3, 3.5, 4}
Make/N=(20,20)/O wave0
SetScale/I x, -1, 1, wave0
SetScale/I y, -1, 1, wave0
wave0 = poly2D(coefs, x, y)
Display; AppendMatrixContour wave0
```

The polynomial is second degree, so the first command above made the wave coefs with six elements because  $(2+1)(2+2)/2 = 6$ .

To fill wave0 with 100 points containing the polynomial  $1 + 2*x + 3*y + 4*x^2 + 4*y^2 + 5*x^3 + 6*y^3$  (note the lack of cross terms) evaluated over the range  $x = (-1, 1)$  and  $y = (-1, 1)$  (the contour plot already made should update with the new data). The first zero eliminates the second-order cross term  $x*y$  and the second and third zeros eliminate the third-order cross terms  $x^2*y$  and  $x*y^2$ :

```
Make/O coefs = {1, 2, 3, 4, 0, 4, 5, 0, 0, 6}
wave0 = poly2D(coefs, x, y)
```

## PolygonArea

### **PolygonArea(xWave, yWave)**

The PolygonArea function returns the area of a simple, closed, convex or nonconvex planar polygon described by consecutive vertices in *xWave* and *yWave*.

A simple polygon has no internal “holes” and its boundary curve does not intersect itself. Both *xWave* and *yWave* must be 1D, real, numerical waves of the same dimensions. The minimum number of vertices is 3. The function uses the shoelace algorithm to compute the area (see theorem 1.3.3 in the reference below). If there is any error in the input, the function returns NaN.

### **Example**

```
Function estimatePi(num)
  Variable num
  Make/O/N=(num+1) xxx,yyy
  xxx=sin(2*pi*x/num)
  yyy=cos(2*pi*x/num)
  printf "Relative Error=%g\r", (pi-PolygonArea(xxx,yyy))/pi
End
```

### **See also**

The **areaXY** and **faverageXY** functions.

### **References**

O'Rourke, Joseph, *Computational Geometry in C*, 2nd ed., Cambridge University Press, New York, 1998.

## popup

### **popup menuList**

The popup keyword is used with Prompt statements in Functions and Macros. It indicates that you want a pop-up menu instead of the normal text entry item in a DoPrompt simple input dialog (or a Macro's missing parameter dialog (archaic)). *menuList* is a string expression containing a list of items, separated by semicolons, that are to appear in the pop-up menu.

Pop-up menus accept both numeric and string parameters. For numeric parameters, the number of the item selected is placed in the variable. Numbering starts from one. For string parameters, the selected item's text is placed in the string variable.

Pop-up items support all of the special characters available for user-defined menu definitions (see **Special Characters in Menu Item Strings** on page IV-96) with the exception that items in pop-up menus are limited to 50 characters, keyboard shortcuts are not supported, and special characters must be enabled.

### **See Also**

**Prompt, DoPrompt, and Pop-Up Menus in Simple Dialogs** on page IV-105.

See **WaveList, TraceNameList, ContourNameList, ImageNameList, FontList, MacroList, FunctionList, StringList, and VariableList** for functions useful in generating lists of Igor objects.

Chapter III-14, **Controls and Control Panels** for details about control panels and controls.

## PopupContextualMenu

**PopupContextualMenu** [*/C=(xpix, ypix)*] *popupStr*

The PopupContextualMenu operation displays a popup menu until the user makes a selection or cancels the menu by clicking outside of its window.

The menu appears at the current mouse position or at the location specified by the /C flag.

### Parameters

*popupStr* specifies the pop-up menu's items. *popupStr* is a semicolon-separated list of items such as "yes;no;maybe;", or a string expression that returns such a list, such as **TraceNameList**.

The menu items can be formatted and checkmarked, like user-defined menus can. See **Special Characters in Menu Item Strings** on page IV-96.

### Flags

*/C=(xpix, ypix)* Sets the coordinates of the menu's top left corner. Units are in pixels relative to the top-most window, such as the MOUSEX and MOUSEY values passed to a window hook. See the window hook example, below and **SetWindow**.  
If /C is not specified, the menu's top left corner appears at the current mouse position.

### Details

PopupContextualMenu sets the following variables:

V_flag	-1:	User cancelled the menu without choosing an item, or there was an error such as an empty <i>popupStr</i> .
	0:	Error, such as an empty <i>popupStr</i> .
	≥1:	1 if the first menu item was chosen, 2 for the second, etc.
S_selection	" "	if the user cancelled or error, else the text of the selected menu item.

### Examples

Formatting a menu item:

```
String checked= "\\M0:!" + num2char(18) + ":" // checkmark code
String items= "first;\M1-;" + checked + "third;" // 2nd is divider, 3rd is checked
PopupContextualMenu items
switch( V_Flag )
  case 1:
    // do something because first item was chosen
    break;
  case 3:
    // do something because first item was chosen
    break;
endswitch
```

Window hook example:

```
SetWindow kwTopWin hook=TableHook, hookevents=1 // mouse down events
Function TableHook(infoStr)
  String infoStr
  Variable handledEvent=0
  String event= StringByKey("EVENT",infoStr)
  strswitch(event)
    case "mousedown":
      Variable isContextualMenu= NumberByKey("MODIFIERS",infoStr) & 0x10
      if( isContextualMenu )
        Variable xpix= NumberByKey("MOUSEX",infoStr)
        Variable ypix= NumberByKey("MOUSEY",infoStr)
        PopupContextualMenu/C=(xpix,ypix) "yes;no;maybe;"
        strswitch(S_selection)
          case "yes":
            // do something because "yes" was chosen
            break
          case "no":
            break
          case "maybe":
            // do something because "maybe" was chosen
            break
        endswitch
      handledEvent=1
```

## PopupMenu

---

```
        endif
    endswitch
    return handledEvent
End
```

### See Also

**Special Characters in Menu Item Strings** on page IV-96 and Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

The **SetWindow** and **PopupMenu** operations.

## PopupMenu

**PopupMenu** [/Z] *ctrlName* [*key* [= *value*]] [, *key* [= *value*]]...

The **PopupMenu** operation creates or modifies a pop-up menu control in the target or named window.

For information about the state or status of the control, use the **ControlInfo** operation.

### Parameters

*ctrlName* is the name of the **PopupMenu** control to be created or changed.

*key* is one of the following parameters:

appearance={*kind* [, *platform*]}

Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

*kind* can be one of **default**, **native**, or **os9**.

*platform* can be one of **Mac**, **Win**, or **All**.

See **Button** and **DefaultGuiControls** for more appearance details.

bodyWidth=*width*

Specifies an explicit size for the body (nontitle) portion of a **PopupMenu** control. By default (bodyWidth=0), the body portion autosizes depending on the current text. If you supply a bodyWidth>0, then the body is fixed at the size you specify regardless of the body text. This makes it easier to keep a set of controls right aligned when experiments are transferred between Macintosh and Windows, or when the default font is changed.

disable=*d*

Sets user editability of the control.

*d*=0: Normal.

*d*=1: Hide.

*d*=2: Draw in gray state; disable control action.

font="*fontName*"

Sets the font used for the pop-up title, e.g., font="Helvetica".

fontSize=*s*

Sets the font size for the pop-up title.

fontStyle=*fs*

*fs* is a binary coded number with each bit controlling one aspect of the font style as follows:

bit 0: Bold.

bit 1: Italic.

bit 2: Underline.

bit 3: Outline (*Macintosh only*).

bit 4: Shadow (*Macintosh only*).

See **Setting Bit Parameters** on page IV-11 for details about bit settings.

help={*helpStr*}

Sets the help for the control. The help text is limited to a total of 255 characters. On Macintosh, the help appears if you turn Igor Tips on. On Windows, the help for the first 127 characters or up to the first line break appears in the status line. If you press F1 while the cursor is over the control, you will see the entire help text. You can insert a line break by putting "\r" in a quoted string.

mode=*m*

Specifies the Pop-up title location.

*m*=0: Title is in pop-up menu.

*m*>0: Title is to the left of pop-up menu, the chosen menu item appears in the pop-up menu, and menu item number *m* is initially selected.

noproc

Specifies that no procedure is to execute when choosing in the pop-up menu.

popColor=( <i>r,g,b</i> )	Specifies the color initially chosen in the color pop-up palette. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535. See the <b>Colors, Color Tables, Line Styles, Markers, and Patterns</b> section.
popvalue= <i>valueStr</i>	Sets the string displayed by the menu when first created, if mode is not zero. See <b>Popvalue Keyword</b> section.
pos={ <i>left,top</i> }	Sets position of pop-up menu in pixels.
proc= <i>procName</i>	Specifies the procedure to execute when the pop-up menu is clicked.
rename= <i>newName</i>	Gives pop-up menu a new name.
size={ <i>width,height</i> }	Sets pop-up menu size in pixels.
title= <i>titleStr</i>	Sets title of pop-up menu to the specified string expression. The title is the text that identifies the purpose of the pop-up menu.
userdata( <i>UDName</i> )= <i>UDStr</i>	Sets the unnamed user data to <i>UDStr</i> . Use the optional ( <i>UDName</i> ) to specify a named user data to create.
userdata( <i>UDName</i> )+= <i>UDStr</i>	Appends <i>UDStr</i> to the current unnamed user data. Use the optional ( <i>UDName</i> ) to append to the named <i>UDStr</i> .
value= <i>popupStr</i>	Specifies the pop-up menu's items. <i>popupStr</i> is a semicolon-separated list of items such as "yes ; no ; maybe", or an expression that returns such a list, such as <b>TraceNameList</b> . You can also create pop-up controls containing colors and line styles; see the <b>Colors, Color Tables, Line Styles, Markers, and Patterns</b> section.
win= <i>winName</i>	Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed. When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy.

**Flags**

/Z No error reporting.

**Details**

The target window, or the window named with the win=*winName* keyword, must be a graph or panel.

The action procedure, which may be a function *or* a macro, has the format:

```
Function procName(ctrlName, popNum, popStr) : PopupMenuControl
    String ctrlName
    Variable popNum          // which item is currently selected (1-based)
    String popStr            // contents of current popup item as string
    ...
End
```

The “: PopupMenuControl” puts the procedure in the Procedure pop-up menu in the PopupMenu Control dialog.

The action procedure for a PopupMenu control can also use a predefined structure **WMPopupAction** as a parameter to the function. The control will use this more efficient method when the function properly matches the structure prototype for a PopupMenu control, otherwise it will use the old-style method.

A PopupMenu action procedure using a structure has the format:

```
Function newActionProcName(PU_Struct)
    STRUCT WMPopupAction &PU_Struct
    ...
End
```

For a PopupMenu control, the **WMPopupAction** structure has members as described in the following table:

**WMPopupAction Structure Members**

Member	Description
char ctrlName[MAX_OBJ_NAME+1]	Control name.
char win[MAX_WIN_PATH+1]	Host (sub)window.
STRUCT Rect winRect	Local coordinates of host window.

## WMPopupAction Structure Members

Member	Description						
STRUCT Rect ctrlRect	Enclosing rectangle of the control.						
STRUCT Point mouseLoc	Mouse location.						
Int32 eventCode	Event that executed the procedure.						
	<table border="1"> <thead> <tr> <th>eventCode</th> <th>Event</th> </tr> </thead> <tbody> <tr> <td>-1</td> <td>Control being killed</td> </tr> <tr> <td>2</td> <td>Mouse up</td> </tr> </tbody> </table>	eventCode	Event	-1	Control being killed	2	Mouse up
eventCode	Event						
-1	Control being killed						
2	Mouse up						
Int32 eventMod	Bitfield of modifiers. See description of MODIFIERS: <i>flags</i> for <b>SetWindow</b> under <b>Unnamed Hooks</b> on page V-505.						
String userdata	Primary (unnamed) user data. If this changes, it is written back automatically.						
Int32 popNum	Item number currently chosen (1-based).						
char popStr[MAXCMDLEN]	Contents of current popup item.						

Action functions should respond only to documented `eventCode` values. Other event codes may be added along with more fields. Although the return value is not currently used, action functions should always return zero.

The constants used to specify the size of structure `char` arrays are internal to Igor Pro and may change.

The value string must be capable of being executed at any time. The expression is stored and executed when the menu is activated to fill the menu before the menu is displayed. This way, a function that returns a list of items, such as **WaveList** or **TraceNameList** can be used to make a pop-up menu that reflects conditions at the time it is used.

However, execution will occur outside the routine that creates the pop-up menu control, so you must not use local variables in the expression.

In pop-up menus, the `#"` syntax (see **When Dependencies are Updated** on page IV-174) permits use of a string expression. Normally, the `#` prefix signifies that the following text must be a literal quoted string. But here, the text can also be a string expression that is evaluated at runtime to obtain the final expression for the pop-up menu. In other words, there is a level of indirection. For example:

```
Function/S sf()
    return "Red;Blue;Green;"
End

Function Panel0()
    NewPanel /W=(150,50,478,250)
    PopupMenu popup0,pos={1,2},size={47,20}
    String s="sf()"
    PopupMenu popup0,mode=1,value= #s + "+\yellow;"
End
```

### Colors, Color Tables, Line Styles, Markers, and Patterns

You can create `PopupMenu` controls for color, color tables, line style (dash modes), markers, and patterns. To do so, simply specify the value string as one of `*COLORPOP*`, `*COLORTABLEPOP*`, `*COLORTABLEPOPNONAMES*`, `*LINESTYLEPOP*`, `*MARKERPOP*`, or `*PATTERNPOP*`. In these modes the body of the control will contain a color box, a color table (gradient), a line style sample, a marker, or a pattern sample.

For these special pop-up menus, `mode=0` ("Title in Box" checked) is not used.

For a line style pop-up menu, the mode value is the line style number plus one. Thus line style 0 (a solid line) is `mode=1`.

For a marker pop-up, the mode value is the marker number plus one, and marker 0 (the + marker) is `mode=1`.

For a pattern pop-up, the mode value is the **SetDrawEnv** fillPat number minus 4, so mode=1 corresponds to fillpat=5, the SW-NE lines fill pattern shown above.

For a color table pop-up, the mode value is the CTabList() index plus 1, so mode=1 corresponds to the first item in the list returned by **CTabList**, which is "Grays":

```
ControlInfo $ctrlName // Sets V_Value
Print StringFromList(V_Value-1,CTabList()) // Prints "Grays"
```

**ControlInfo** also returns the color table name in S\_Value.

To set the pop-up to a given color table name, you can use code like this:

```
Variable m = 1 + WhichListItem(ctabName, CTabList())
PopuMenu $ctrlName mode=m
```

For color pop-up menus, you set the current value using the popColor=(*r, g, b*) keyword. On output (via the popStr parameter of your action procedure or via the S\_value output from **ControlInfo**) the color is encoded as "(*r,g,b*)" where *r, g,* and *b* are numbers. To get these numerical values, you can extract them from the string using the MyRGBstrToRGB function below or use ControlInfo which sets V\_Red, V\_Green, V\_Blue. The following example demonstrates the line style and color pop-up menus. To run the example, copy the following code to the procedure window of a new experiment and then run the panel macro.

```
Window Panel0() : Panel
  PauseUpdate; Silent 1 // building window ...
  NewPanel /W=(150,50,400,182)
  PopupMenu popup0,pos={74,31},size={96,20},proc=ColorPopMenuProc,title="colors"
  PopupMenu popup0,mode=1,popColor= (0,65535,65535),value= "*COLORPOP*"
  PopupMenu popup1,pos={9,68},size={221,20},proc=LSytlePopMenuProc,title="line styles"
  PopupMenu popup1,mode=1,value= "*LINESTYLEPOP*"
EndMacro
```

```
Function ColorPopMenuProc(ctrlName,popNum,popStr) : PopupMenuControl
  String ctrlName
  Variable popNum
  String popStr

  Variable r,g,b
  MyRGBstrToRGB(popStr,r,g,b) // One way to get r, g, b
  print popStr," gives: ",r,g,b

  ControlInfo $ctrlName // Another way: sets V_Red, V_Green, V_Blue
  Printf "ControlInfo returned (%d,%d,%d)\r", V_Red, V_Green, V_Blue
End
```

// Take (r,g,b) string and extract out numeric r,g,b values

```
Function MyRGBstrToRGB(rgbStr,r,g,b)
  String rgbStr
  Variable &r, &g, &b

  r= str2num(rgbStr[1,inf])
  variable spos= strsearch(rgbStr,"",0)
  g= str2num(rgbStr[spos+1,inf])
  spos= strsearch(rgbStr,"",spos+1)
  b= str2num(rgbStr[spos+1,inf])
  return 1
End
```

```
Function LSytlePopMenuProc(ctrlName,popNum,popStr) : PopupMenuControl
  String ctrlName
  Variable popNum
  String popStr

  print "style:",popNum-1
End
```

### Popvalue Keyword

There are times when the displayed value cannot be determined and saved such that it can be displayed when the pop-up menu is recreated. For instance, because window recreation macros are evaluated in the root folder, a pop-up menu of waves may not contain the correct list when a panel is recreated. That is, the intention may be to have the menu show a particular wave from a data folder other than root. When the panel recreation macro runs, the function that lists waves will list waves in the root data folder. The desired selection may be wrong or nonexistent.

Similarly, a pop-up menu of fonts may need to display a particular font upon recreation on a different computer having a different list of fonts. The mode=*m* keyword probably won't pick the correct font from the new list.

## PopupMenuControl

---

The solution to these problems is to save the correct selection with the `popvalue=valueStr` keyword. The list function will not be executed when the menu is first created. If the menu is popped, the list function will be evaluated, and the correct list will be displayed then.

It is a good idea to set the `mode=m` keyword to the correct number, if it is known. That way, when the menu is popped the correct item is chosen.

Normally you can let Igor redraw the pop-up menu when it redraws the graph or control panel containing it. However, there are situations in which you may want to force the pop-up menu to be redrawn. This can be done using the **ControlUpdate** operation.

### See Also

The **ControlInfo** operation for information about the control. The **ControlUpdate**, **WaveList**, and **TraceNameList** operations. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **GetUserData** operation for retrieving named user data.

## PopupMenuControl

### PopupMenuControl

PopupMenuControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined pop-up menu control. See **Procedure Subtypes** on page IV-149 for details.

## PossiblyQuoteName

### PossiblyQuoteName (nameStr)

The PossiblyQuoteName function returns the input name string if it conforms to the rules of standard wave or Data Folder names. If it does not, then the name is returned in single quotes. This is used when generating a command string that you will pass to the Execute command. You might get the input name string from a function such as **NameOfWave** or **CsrXWave**.

### Examples

```
Print PossiblyQuoteName("wave0")           // prints wave0
Print PossiblyQuoteName("wave 0")          // prints 'wave 0'
```

### Details

See **Programming with Liberal Names** on page IV-121 for an example.

## Preferences

### Preferences [/Q] [newPrefsState]

The Preferences operation sets or displays the state of user preferences.

User preferences affect the creation of *new* graphs, panels, tables, layouts, notebooks, procedure windows, and the command window. They also affect the appearance of waves appended to graphs and tables, and objects appended to layouts.

### Parameters

If *newPrefsState* is present, it sets the state of user preferences as follows:

```
newPrefsState=0:    Preferences off (use factory defaults).
newPrefsState=1:    Preferences on.
```

If *newPrefsState* is omitted, the state of user preferences is printed in the history area.

### Flags

```
/Q                Disables printing to the history.
```

### Details

The Preferences operation sets the variable `V_flag` to the state of user preferences that were in effect *before* the Preferences command executed: 1 for on, 0 for off.

You can also set the state of Preferences with the Misc menu.

Under most circumstances we want procedures to be independent of preferences so that a particular procedure will do the same thing regardless of the state of preferences. To achieve this, preferences are automatically off when you initiate procedure execution. When execution is complete, the state of preferences is restored to what it was before.

If you want preferences to be in effect during procedure execution, you must turn it on with the Preferences operation.

If the preferences setting is changed by a procedure, the effect of the call is propagated down the calling chain. If a macro changes the preferences setting, that change is undone when the macro returns. If a function changes the preferences setting, the change persists after the function returns. However, even with a function, the changed preferences state does not persist when Igor regains control.

### Examples

```
Function Test()
    Variable oldPrefState
    Preferences 1; oldPrefState=v_flag          // remember prefs setting
    Make wave0=x
    Display wave0                               // Display uses preferences
    Preferences oldPrefState                    // put prefs back, like a macro would
End
```

### See Also

Chapter III-17, **Preferences**.

## PrimeFactors

### PrimeFactors [/Q] *inNumber*

PrimeFactors calculates the prime factors of *inNumber*. By default factors are printed in the history and are also stored in the wave *W\_PrimeFactors* in the current data folder.

### Flags

/Q            Suppresses printing of factors in the history area.

### Details

The largest number that this operation can handle is  $2^{32}-1$ .

## Print

### Print [*flags*] *expression* [, *expression*]...

The Print operation prints the evaluated expressions in the history area.

### Parameters

An expression can be a wave, a numeric expression (e.g.,  $3*\pi/4$ ), a string expression (e.g., "Today is " + date()), or a individual structure element or an entire structure variable.

### Flags

/C            Evaluates all numeric expressions as complex.

/D            Prints a greater number of digits.

/F            Prints numeric wave data (1D and 2D waves only) using "nice," easily readable formatting.

/LEN=*len*    Sets the string break length to *len* number of characters (default is 200).

/S            Obsolete. Numeric results are printed with a moderate number of digits whether you use /S or not. To print more digits, use /D.

/SR           Prints a wave subrange for expressions that start as "*waveName*[ ". Without /SR, such an expression is taken as the start of a numeric expression such as *wave* [ 3 ] -*wave* [ 2 ]. (You can still use *wave*[*prt*] but only if it does not start the numeric expression.)

Wave subrange printing is not done with /F.

You can specify a single row or column using [*r*] syntax. For example, to print column 4 of a matrix, use:

```
Print mymat[ ][4]
```

### Details

Numeric expressions are always evaluated in double precision. The /D flag just controls the number of digits displayed.

Print determines if an expression is real, complex, or string from the first symbol in the expression. Usually this works fine, but occasionally Print guesses wrong and you may have to rearrange your expression. For example:

```
Print 1+cmplx(1,2)
```

## printf

---

will give an error because the first symbol, "1", is real but the expression should be complex. Changing this to

```
Print cmplx(1,2)+1
```

will work.

Print will break long string expressions into multiline pieces. If there are no natural breaks (carriage returns or semicolons) within a default length, then it will break the string arbitrarily.

The default line length is 200 chars or it can be set using the /LEN flag. The maximum number of characters that can be printed on a line in the History area is 400.

When printing waves, you can use either formatted (specified by /F) or unformatted (default) methods. Unformatted output is in an executable syntax for each printed line: `wave={ }`.

**Note:** Executing lines printed from floating point waves will not exactly reproduce the source data due to round-off or insufficient digits in the printed output.

Printing formatted wave data gives easily (human) readable output, and works best for small 1D and 2D waves. If the data are too large or in an unsupported format (3D or greater, or the wave is text), then the output will be unformatted. Formatting is done using spaces, so the output will look best in a fixed-width font.

Printed wave data, both formatted and unformatted, are limited to no more than 100 lines of output. When the line limit is exceeded a warning message will be printed at the end of the truncated output. For text waves, output is limited to 50 characters of each string element, and there is no warning when a string is truncated.

### See Also

The `printf` operation.

## printf

```
printf formatStr [, parameter [, parameter]...]
```

The `printf` operation prints formatted output to the history area.

### Parameters

*formatStr* is a string which specifies the formatting of the output.

The number of parameters depends on the number of conversion specifications in the format string. Lack of agreement between the type of the parameter, string or numeric, and the corresponding conversion specification in *formatStr* yields indeterminate results.

### Details

The `printf` operation supports numeric (real only) and string fields from structures. All other field type will cause a compile error.

The *formatStr* contains literal text and conversion specifications.

A conversion specification starts with the % character and ends with a conversion character (for example, g, e, f, d, or s as illustrated below). In between the % and the conversion character you may include one or more flag characters, a field width specifier, and a precision specifier. The first % corresponds to the first parameter, the second % corresponds to the second parameter, etc. If *formatStr* contains no % characters, no parameters are expected.

Here are some simple examples. `numVar` is a numeric variable and `strVar` is a string variable.

```
printf "The answer is: %g\r", numVar
printf "Created wave %s\r", strVar
printf "Created wave %s, %d points\r", strVar, numVar
```

%g is a general-purpose format (floating point or scientific notation) that represents the value of `numVar`.

%d is an integer format that represents the value of `numVar`. %s specifies that the corresponding parameter (`strVar`) is a string.

The "\r" in these examples appends a carriage return to the end of the printed text.

Here is a complex example using all of these elements of a conversion specification:

```
printf "%+15.4f\r", 1e6*PI
```

This prints +3141592.6536

The “+” is a flag character that puts a “+” or “-” character in front of the number. The “15” is a field width specifier that prints the number in a field of at least 15 characters. The “4” is a precision specifier that prints four digits after the decimal point. “f” uses a floating point format.

The most common conversions characters are “f” for floating point, “g” for general, “d” for decimal, and “s” for string. They are interpreted as for the printf() function in the C programming language.

The escape codes \t and \r represent the tab and return characters respectively. See **Escape Characters in Strings** on page IV-13 for more information.

The supported flag characters and their meanings are as follows:

-	Left align the result in the field.
+	Put a plus or minus sign before the number.
<space>	Put a space before a positive number.
#	Specifies alternate form for e, f, g, and x formats.

The meaning of the precision specifier depends on the numeric format (%g, %e, %f, %d, etc.) being used:

e, E, f	Precision specifies number of digits after decimal point.
g, G	Precision specifies maximum number of significant digits.
d, o, u, x, X	Precision specifies minimum number of digits.

You can replace both the field width and precision specifiers with an asterisk. This gets the field width or precision specifier from a parameter. For example:

```
printf "%*.*f\r" 4, 3, 1e6*PI
```

means that the field width is 4 and the precision is 3. You could use numeric expressions instead of the literal numbers to control the field width and precision algorithmically.

Here is a complete list of the conversion characters supported by printf:

f	Converts a numeric parameter as [-]ddd.ddd, where the number of digits after the decimal point is determined by the precision specifier and defaults to 6. If the # flag is present, a decimal point will be used even if there are no digits to the right of it.
e, E	Converts a numeric parameter as [-]d.ddde+/-dd, where the number of digits after the decimal point is determined by the precision specifier and defaults to 6. If you use “E” instead of “e” then printf uses a capital “E” in the number. If the # flag is present, a decimal point will be used even if there are no digits to the right of it.
g, G	Converts a numeric parameter using “f” or “e” style conversion depending on the magnitude of the number. “e” is used if the exponent is less than -4 or greater than the precision. “G” uses “f” or “E” style conversion. If the # flag is present, a decimal point will be used even if there are no digits to the right of it and trailing zeros will not be removed.
d, o, u	Converts a numeric parameter as a signed decimal integer, unsigned octal integer or unsigned decimal integer, truncating any fractional part. The precision defaults to one and specifies the minimum number of digits to print.
x, X	Converts a numeric parameter as an unsigned hexadecimal integer, truncating any fractional part. The “x” style uses lower case for the hexadecimal numerals “abcdef” where the “X” style uses upper case. The precision defaults to one and specifies the minimum number of digits to print. If the # flag is present, the string “0x” or “0X” is prepended to the number if it is not zero.
s	Converts a string parameter which can contain no more than 1000 characters. If a precision is specified, it sets the maximum number of characters from the string parameter to be printed.
b	WaveMetrics extension. Converts a numeric parameter to binary.
c	Converts a numeric parameter to a single character.
%	Prints a % sign. No parameter is used.
%W	WaveMetrics extension. See description below.

Igor also supports a non-C, WaveMetrics extension to the conversion characters recognized by printf. This conversion specification starts with “%W”. It is followed by a flag digit and a format character. For example, `printf "%W0Ps", 12.345E-6`

## PrintGraphs

---

prints 12.345000 $\mu$ s. In this example, the “%W0” introduces the WaveMetrics conversion specification. The “0” (zero) following the “W” is the flag digit. The “P” that follows is the format specifier character, which prints the number using a prefix, in this case, “ $\mu$ ”.

There is only one WaveMetrics format specifier character, “P”, which prints using a prefix such as  $\mu$ , m, k, or M. It recognizes two flag-digits, “0” or “1”. Option “0” prints with no space between the numeric part and the prefix character while flag “1” prints with 1 space. Numbers greater than tera or less than femto print using a power of ten notation. Here are a few examples:

```
printf "%.2W0PHz", 12.342E6      // prints 12.34MHz
printf "%.2W1PHz", 12.342E6      // prints 12.34 MHz
printf "%.0W0Ps", 12.342E-6      // prints 12 $\mu$ s
printf "%.0W1Ps", 12.342E-9      // prints 12 ns
```

## PrintGraphs

**PrintGraphs** [*flags*] *graphSpec* [, *graphSpec*]...

The PrintGraphs operation prints one or more graphs.

PrintGraphs prints one or more graphs on a single page from the command line or from a procedure. The graphs can be overlaid or positioned any way you want.

### Parameters

The *graphSpec* specifies the name of a graph to print, the position of the graph on the page and some other options.

### Flags

*/C=num* Renders graphs in black and white (*num*=0) or in color (*num*=1; default).  
*/D* Disables high resolution printing. This flag is of use only on Macintosh. It has no effect on Windows.  
*/G=grout* Specifies grout, the spacing between objects, for tiling in prevailing units.  
*/I* Coordinates are in inches.  
*/M* Coordinates are in centimeters.  
*/R* Coordinates are in percent of page size (see **Examples**).  
*/S* Stacks graphs.  
*/T* Tiles graphs.

### Details

Graph coordinates are in inches (*/I*) or centimeters (*/M*) relative to the top left corner of the physical page. If none of these options is present, coordinates are assumed to be in points.

The form of a *graphSpec* is:

***graphName*** [(*left*, *top*, *right*, *bottom*)] [*/F=f*] [*/T*]

Here are some examples:

```
// Take size and position from window size and position.
PrintGraphs Graph0, Graph1
// Specify size and position explicitly.
PrintGraphs/I Graph0(1, 1, 6, 5)/F=1, Graph1(1, 6, 6, 10)/F=1
```

If the coordinates are missing and the */T* or */S* flags are present before *graphSpec* then the graphs are tiled or stacked. If the coordinates are missing but no */T* or */S* flags are present then the graph is sized and positioned based on its position on the desktop.

Finally there are these *graphSpec* options, which appear after the graph name:

*/F=f* Specifies a frame around the graph.  
*f*=1: Single frame.  
*f*=2: Double frame.  
*f*=3: Triple frame.  
*f*=4: Shadow box frame.  
*/T* Graph is transparent. This allows special effects when graphs are overlaid.

For this to be effective, the graph and its contents must also be transparent. Graphs are transparent only if their backgrounds are white. Annotations have their own transparent/opaque settings. PICTs may have been created transparent or opaque; an opaque PICT cannot be made transparent.

### Examples

You can put an entire *graphSpec* into a string variable and use the string variable in its place. In this case the name of the string variable must be preceded by the \$ character. This is handy for printing from a procedure and also keeps the PrintGraphs command down to a reasonable number of characters. For example:

```
String spec0, spec1, spec2
spec0 = "Graph0(1, 1, 6, 5)/F=1"
spec1 = "Graph1(1, 6, 6, 10)/F=1"
spec2 = "" // PrintGraphs will ignore spec2.
PrintGraphs/I $spec0, $spec1, $spec2
```

If you use a string for a *graphSpec* and that string contains no characters then PrintGraphs will ignore that *graphSpec*.

## PrintLayout

**PrintLayout** [*/C/D*] *winName*

The PrintLayout operation prints the named page layout window.

### Parameters

*winName* is the window name of the page layout to print.

### Flags

*/C=num* Renders graphs, tables, and annotations in black-and-white (*num=0*) or in color (*num=1*; default). It has no effect on pictures, which are colored independently.

*/D* Prints the layout at the default resolution of the output device. Otherwise it is printed at the highest resolution. This flag is of use only on Macintosh. It has no effect on Windows.

### Details

Normally page layouts are printed at the highest available resolution of the output device (printer, plotter, or whatever). On Macintosh, it may not work properly at high resolution with some unusual output devices. If this happens, you can try using the */D* flag to see if it works properly at the default resolution.

## PrintNotebook

**PrintNotebook** [*flags*] *winName*

The PrintNotebook operation prints the named notebook window.

### Parameters

*winName* is the window name of the notebook to print.

### Flags

*/B=hiResMethod* *Macintosh only*; this flag has no effect on Windows.

*hiResMethod=1*: Print HiRes PICTs using high resolution bitmaps.

*hiResMethod=0*: Don't print HiRes PICTs using high resolution bitmaps.

*hiResMethod=-1*: Print using the default method. Prints HiRes PICTs using high resolution bitmaps and is the same as method 1.

*/P=(startPage,endPage)* Specifies a page range to print. 1 is the first page.

*/S=selection*

*selection=0*: Print entire notebook (default).

*selection=1*: Print selection only.

### Details

If no */B* flag is given, the default method of handling HiRes PICTs is used (*/B=1*). Printing of HiRes PICTs is not well supported on the Macintosh, so by default it prints them using temporary high resolution bitmaps. If a future version of the Mac OS improves in this respect, we will change the default method to print directly.

### See Also

Chapter III-1, **Notebooks**.

### PrintSettings

**PrintSettings** [/I /M /W=*winName*] [*copySource=source*, *orientation=o*,  
*margins={left,top,right,bottom}*, *scale=s*, *colorMode=m*, *getPrinterList*,  
*getPrinter*, *setPrinter=printerNameStr*, *getPageSettings*, *getPageDimensions*]

The PrintSettings operation gets or sets parameters associated with printing, such as a list of available printers or page setup information for a particular window.

When getting or setting page setup information, PrintSettings acts on a particular window called the destination window. The destination window is the top graph, table, page layout, or notebook window or the window specified by the /W flag.

PrintSettings can not act on page setup records associated with the command window, procedure windows, help windows, control panel, XOP windows, or any type of window other than graphs, tables, page layouts, and notebooks.

The PrintSettings operation services the keywords in the order shown above, not in the order in which they appear in the command. Thus, for example, the getPageSettings and getPageDimensions keywords report the settings after all other keywords are executed.

#### Flags

- /I                    Measurements are in inches. If both /I and /M are omitted, measurements are in points.
- /M                    Measurements are in centimeters. If both /I and /M are omitted, measurements are in points.
- /W=*winName*        Acts on the page setup record of the graph, table, page layout, or notebook window identified by *winName*. If *winName* is omitted or if *winName* is " ", then it used the page setup for the top window.

#### Keywords

- colorMode=m*        Sets the color mode for the page setup to monochrome (*m=0*) or to color (*m=1*).  
This keyword does nothing on Macintosh because it is not supported by Mac OS X.
- copySource=source* Copies page setup settings from the specified source to the destination window. *source* can be the name of a graph, table, page layout, or notebook window or it can be one of the following special keywords:
- Default\_Settings: Sets the page setup record to the default for the associated printer as specified by the printer driver.
  - Factory\_Settings: Sets the page setup record to the WaveMetrics factory default. This is the page setup you get when creating a new window with user preferences turned off.
  - Preferred\_Settings: Sets the page setup record to the user preferred page setup. This is the page setup you get when creating a new window with user preferences turned on. Because there is only one page setup for all graphs and one page setup for all tables, this has no effect when the destination window is a graph or table. It does work for layouts and notebooks.
- getPageDimensions* Returns page dimensions via the string variable *S\_value*, which contains keyword-value pairs that can be extracted using **NumberByKey** and **StringByKey**. See **Details** for keyword-value pair descriptions.
- getPageSettings*   Returns page setup settings in the string variable *S\_value*, which contains keyword-value pairs that can be extracted using **NumberByKey** and **StringByKey**. See **Details** for keyword-value pair descriptions.
- getPrinter*         Returns the name of the selected printer for the destination window in the string variable *S\_value*. On Macintosh the returned value will be " " if the setPrinter keyword was never used on the destination window. This means that the window will use the operating system's "current printer".
- getPrinterList*    Returns a semicolon-separated list of printer names in the string variable *S\_value*.
- Mac OS 9:           Does not work and returns an error, although Apple documentation suggests that it should work. Therefore you must use **IgorInfo** to check what OS you have and not use this keyword with Mac OS 9.

Mac OS X:	Returns a list of printers added through Print Center.
Windows 98:	Returns the names of local printers and network printers. This can take a while.
Windows NT, 2000, and XP:	Returns the names of any local printers and names of network printers to which the user has made previous connections. This should execute quickly.

`margins={left, top, right, bottom}`

Sets the page margins. Dimensions are in points unless /I or /M is used.

The margins are clipped so that they are no smaller than the minimum allowed by the printer driver and no larger than one-half the size of the paper.

The terms *left*, *top*, *right*, and *bottom* refer to the sides of the page after possible rotation for landscape orientation.

Passing zero for all four margins sets the margins to the minimum margin allowed by the printer.

On Macintosh only, passing -1 for all four margins sets the margins to whatever minimum margin is allowed by the printer, even if the printer is changed later. This is how Igor Pro behaved on Macintosh prior to the creation of the PrintSettings operation, when the minimum printer margins were always used.

`orientation=o`

Sets the paper orientation to portrait ( $o=0$ ) or to landscape ( $o=nonzero$ ).

`scale=s`

Sets the page scaling in percent.  $s$  is clipped to the range 5 to 5000. A value of 50 prints graphics at one-half the normal size. Some printer drivers do not support scaling in which case the scale keyword does nothing. Many Windows printer drivers that do support scaling still do not work with the scale keyword because their scaling support does not use the standard Windows technique.

`setPrinter=printerNameStr`

Sets the selected printer for the destination window.

SetPrinter attempts to preserve orientation, margins, scale, and color mode but other settings may revert to the default state.

On Mac OS 9, this does not work and returns an error, although Apple documentation suggests that it should work. Therefore you must use **IgorInfo** to check what OS you are using and not use this keyword on Mac OS 9.

*printerNameStr* is a name as returned by the `getPrinterList` keyword and may not be identical to the name displayed in various dialogs. For example, on Mac OS X, the printer name "DESKJET 840C" is returned by `getPrinterList` as "DESKJET\_840C". The latter is the "Queue Name" displayed by the Mac OS X Print Center or Printer Setup Utility programs.

If *printerNameStr* is "", the printer for the destination window is set to the default state. This means different things depending on the operating system:

Mac OS X:	The destination window will use the operating system's "current printer", as if the <code>setPrinter</code> keyword had never been used.
Windows 2000, XP, or later:	The destination window will use the system default printer.
Windows 95, 98, and NT:	Has no effect at all because these operating systems do not provide the necessary support for this feature.

If you receive an error when using `setPrinter`, use the `getPrinterList` keyword to verify that the printer name you are using is correct. Verify that the printer is connected and turned on.

Windows printer names are sometimes UNC names of the form "\\Server\Printer". You must double-up backslashes when using a UNC name in a literal string. See **UNC Paths** on page III-383 for details.

## PrintSettings

---

### Details

All graphs in the current experiment share a single page setup record so if you change the page setup for one graph, you change it for all graphs.

All tables in the current experiment share a single page setup record.

Each page layout window has its own page setup record.

Each notebook window has its own page setup record.

The keyword-value pairs for the `getPageSettings` keyword are as follows:

Keyword	Information Following Keyword
ORIENTATION:	0 if the page is in portrait orientation, 1 if it is in landscape orientation.
MARGINS:	The left, top, right, and bottom margins in points, separated by commas.
SCALE:	The page scaling expressed in percent. 50 means that the graphics are drawn at 50% of their normal size.
COLORMODE:	0 for black&white, 1 for color. This is not supported on Macintosh and always returns 1.

The keyword-value pairs for the `getPageDimensions` keyword are as follows:

Keyword	Information Following Keyword
PAPER:	The left, top, right, and bottom coordinates of the paper in points, separated by commas. The top and left are negative numbers so that the page can start at (0,0).
PAGE:	The left, top, right, and bottom coordinates of the page in points, separated by commas. The term page refers to the part of the paper inside the margins. The top/left corner of the page is always at (0, 0).
PRINTAREA:	The left, top, right, and bottom coordinates of the page in points, separated by commas. The print area is the part of the paper on which printing can occur, as determined by the printer. This is equal to the paper inset by the minimum supported margins. The top and left are negative numbers so that the page can start at (0,0).

### Examples

For an example using the `PrintSettings` operation, see the `PrintSettings Tests` example experiment file in the "Igor Pro Folder:Examples:Testing & Misc" folder.

Here are some simple examples showing how you can use the `PrintSettings` operation.

```
Function GetOrientation(name) // Returns 0 (portrait) or 1 (landscape)
  String name // Name of graph, table, layout or notebook
  PrintSettings/W=$name getPageSettings
  Variable orientation = NumberByKey("ORIENTATION", S_value)
  return orientation
End

Function SetOrientationToLandscape(name)
  String name // Name of graph, table, layout or notebook
  PrintSettings/W=$name orientation=1
End

Function/S GetPrinterList()
  // PrintSettings getPrinterList does not work on Mac OS 9
  String info = IgorInfo(3)
  if (strsearch(info,"Macintosh Carbon",0) >= 0)
    return "Default"
  endif
  PrintSettings getPrinterList
  return S_value
End

Function SetPrinter(destWinName, printerName)
  String destWinName, printerName
  // PrintSettings setPrinter does not work on Mac OS 9
  String info = IgorInfo(3)
  if (strsearch(info,"Macintosh Carbon",0) >= 0)
```

```

        return -1
    endif
    PrintSettings/W=$destWinName setPrinter=printerName
    return 0
End

```

## PrintTable

**PrintTable** [**/P=(startPage,endPage)** **/S=selection**] *winName*

The PrintTable operation prints the named table window.

### Parameters

*winName* is the window name of the table to print.

### Flags

*/P=(startPage,endPage)* Specifies a page range to print. 1 is the first page.  
 If */P* is omitted all pages are printed unless */S* is used.

*/S=selection*            *selection=0:*    Print entire table (default).  
                              *selection=1:*    Print selection only.

### See Also

Chapter II-11, **Tables**.

## Proc

**Proc** *macroName*([*parameters*]) [**:macro type**]

The Proc keyword introduces a macro that does not appear in any menu. Otherwise, it works the same as **Macro**. See **Macro Syntax** on page IV-80 for further information.

## ProcedureText

**ProcedureText**(*macroOrFunctionNameStr* [, *linesOfContext* [, *procedureWinTitleStr* ]])

The ProcedureText function returns a string containing the text of the named macro or function as it exists in some procedure file, optionally with additional lines that are before and after to provide context or to collect documenting comments.

### Parameters

*macroOrFunctionNameStr* identifies the macro or function. It may be just the name of a global (nonstatic) procedure, or it may include a module name, such as "myModule#myFunction" to specify the static function myFunction in a procedure window that contains a `#pragma ModuleName=myModule` statement.

*linesOfContext* optionally specifies the number of lines around the function to include in the returned string. The default is 0 (no additional contextual lines of text are returned).

Setting *linesOfContext* to -1 returns lines before the procedure that are not part of the preceding macro or function. Usually these lines are comment lines describing the named procedure. Blank lines are omitted.

Setting *linesOfContext* to a positive number returns that many lines before the procedure and after the procedure. Blank lines are not omitted.

The optional *procedureWinTitleStr* can be the title of a procedure window (such as "Procedure" or "File Name Utilities.ipf"). The text of the named macro or function in the specified procedure window is returned.

You can use *procedureWinTitleStr* to select one of several static functions with identical names among different procedure windows, even if they do not use a `#pragma moduleName=myModule` statement.

### Advanced Parameters

If `SetIgorOption IndependentModuleDev=1`, *procedureWinTitleStr* can also be a title followed by a space and, in brackets, an independent module name. In such cases ProcedureText retrieves function text from the specified procedure window and independent module. (See **The IndependentModule Pragma** on page IV-40 for independent module details.)

For example, in a procedure file containing:

```

#pragma IndependentModule=myIM
#include <Axis Utilities>

```

## ProcGlobal

---

A call to ProcedureText like this:

```
String text=ProcedureText("HVAxisList",0,"Axis Utilities.ipf [myIM]")
```

will return the text of the HVAxisList function located in the Axis Utilities.ipf procedure window, which is normally a hidden part of the myIM independent module.

You can see procedure window titles in this format in the Windows→Procedure Windows menu when SetIgorOption IndependentModuleDev=1 and when an experiment contains procedure windows that comprise an independent module, as does #include <New Polar Graphs>.

procedureWinTitleStr can also be just an independent module name in brackets to retrieve function text from any procedure window that belongs to the named independent module:

```
String text=ProcedureText("HVAxisList",0,"[myIM]")
```

### See Also

The **ModuleName Pragma** on page IV-40 and **The IndependentModule Pragma** on page IV-40.

The **WinRecreation** and **FunctionList** functions.

## ProcGlobal

### ProcGlobal#procPictureName

The ProcGlobal keyword is used with Proc Pictures to avoid possible naming conflicts with any other global pictures in the experiment. When you add a picture to an experiment using the Pictures dialog, such a picture is global in scope and may potentially have the same name as a Proc Picture. When a Proc Picture is global (and only then), you should use the ProcGlobal keyword to make sure that the Proc Picture is used with your code and to avoid confusion with pictures in the Pictures dialog.

### See Also

See **Proc Pictures** on page IV-44 for details. **Pictures Dialog** on page III-406.

## Project

**Project** [/C={long,lat}/M=method /P={p1,p2,...}] *longitudeWave*, *latitudeWave*

The Project operation calculates projections of XY data, which most often are longitude and latitude waves of geographic coordinates. The output waves are W\_XProjection and W\_YProjection. Longitude and Latitude are in degrees.

### Parameters

*longitudeWave* is the name of the wave supplying the longitude or equivalent coordinates. *latitudeWave* is the name of the wave supplying the latitude or equivalent coordinates.

### Flags

/C={long,lat}	Specifies longitude and latitude center of projection. By default long=0 and lat=90.
/M=method	Indicates the type of projection. <i>method</i> can be one of the following: 0: Orthographic (default). 1: Stereographic. 2: Gnomonic. 3: General perspective. 4: Lambert equal area. 5: Equidistant. 6: Mercator. 7: Transverse Mercator. 8: Albers Equal Area conic.
/P={p1,p2,...}	One or more parameters required by a particular projection. See the following sections for parameters required by the various projections.

### Gnomonic

Here there is one extra parameter that defines the boundaries based on the angle. The specific expression for the limit is that  $\cos(c)$  in Eq. (5-3) of Snyder is greater than the specified parameter:

```
/P={cos(c)}
```

The actual transformation uses Eqs. (22-4) and (22-5) of Snyder with  $k'$  given by (22-3).

### General Perspective

Here there is one extra parameter that defines the boundaries based on the angle. The specific expression for the limit is that  $\cos(c)$  in Eq. (5-3) of Snyder is greater than the specified parameter.

The actual transformation uses Eqs. (22-4) and (22-5) with  $k'$  given by (22-3). Here we specify the height  $H$  is units of sphere radius. The tilt of the plane is specified by  $\omega$  and  $\gamma$  following the notation of Snyder page 175.

The parameters actually specified by the command are:

$/P=\{H, \omega, \gamma, \text{deltax}, \text{deltay}\}$

$H$  is the height (in radii) above the surface of the earth,  $\gamma$  is the azimuth east of north of the Y axis, and  $\omega$  is the tilt angle or the angle between the projection plane and the tangent plane. The x output will be limited to  $\pm \text{deltax}$  and the y output will be limited to the range  $\pm \text{deltay}$ .

### Mercator

This projection requires the following parameters:

$/P=\{\text{minLong}, \text{maxLong}, \text{minLat}, \text{maxLat}\}$

If  $/P$  is not specified, the default is  $\{0,360,-90,90\}$

Note that this projection flips the sign of y when  $\cos(\text{longitude}-\text{long}_0)$  changes sign. If you are plotting a continuous path in which consecutive points exhibit the sign change, you should add a NaN entry in the wave so that the path does not wrap.

### Albers Equal Area Conic

This projection requires:

$/P=\{\text{minLong}, \text{maxLong}, \text{minLat}, \text{maxLat}, \text{Phi1}, \text{Phi2}\}$

$\text{Phi1}$  and  $\text{Phi2}$  are the specification of the two standard parallels, the other four parameters determine the boundary of the map area for display.

### References

Snyder, John P., *Map Projections — A Working Manual*, U.S.G.S. Professional Paper 1395, U.S. Government Printing Office, Washington D.C., 1987, reprinted 1989, 1994, 1997 with corrections.

## Prompt

**Prompt *variableName*, *titleStr* [, *popup*, *menuListStr*]**

The Prompt command is used in functions for the simple input dialog and in macros for the missing parameter dialog. Prompt supplies text to describe *variableName* to the user, and optionally provides a pop-up menu of choices for the value of *variableName*.

### Parameters

*variableName* is the name of a macro input parameter or function variable.

*titleStr* is a string or string expression containing the text to present in the dialog to describe what *variableName* is. This string should be short if the number of items exceeds 5 (when the dialog uses two columns).

The optional keyword *popup* is used to provide a pop-up list of choices for the values of *variableName*. If *popup* is used, then *menuListStr* is required.

*menuListStr* is a string or string expression that contains a semicolon-separated list of choices for the value of *variableName*. If *variableName* is a string, choosing from this list will set the string to the selection. If it is a numeric variable, then it is set to the item number of the selection (if the first item is selected, the numeric variable is set to 1, etc.).

### Details

In macros, the Prompt command must follow the macro Variable and String parameter declarations, and precede any executing macro statements.

Prompt may be used anywhere within the body of a function, but must precede any DoPrompt that uses the Prompt variable.

## PulseStats

*menuListStr* may be continued on succeeding lines only in macros, as long as no comment is appended to the Prompt line. The additional lines should start with a semicolon, and are appended to the *menuListStrs* on preceding lines.

### Examples

```
Macro SampleMacro(xvar,wv)
  Variable xvar
  String wv
  Prompt xvar,"enter x range"
  Prompt wv,"the wave",popup,WaveList("*",";","")+";_none_"
  // (your code here)
End
```

Note that there must be no blank lines between the Macro declaration and the last Prompt statement.

This macro will produce the following dialog if it is chosen from the Macros menu:

### See Also

Also see **The Simple Input Dialog** on page IV-104; the **DoPrompt** and **popup** keywords.

## PulseStats

### PulseStats [*flags*] *waveName*

The PulseStats operation produces simple statistics on a region of the named wave that is expected to contain three edges as shown below. If more than three edges exist, PulseStats works on the first three edges it finds.

PulseStats handles other cases in which there are only one or two edges.

### Flags

*/A=n*

Determines *startLevel* and *endLevel* automatically by averaging *n* points centered at *startX* and *endX*. This does not work in case 2, which requires that you use the */L* flag. Default is */A=1*.

---

<code>/B=box</code>	Sets box size for sliding average. This should be an odd number. If <code>/B=box</code> is omitted or <code>box</code> equals 1, no averaging is done.
<code>/F=f</code>	Specifies levels 1, 2, and 3 as a fraction of $(endLevel - startLevel)$ : $level1 = level2 = level3 = f * (endLevel - startLevel) + startLevel$ $f$ must be between 0 and 1. The default value is 0.5 which sets the levels to midway between the base levels.
<code>/L=(startLevel, endLevel)</code>	Sets $startLevel$ and $endLevel$ explicitly.
<code>/M=dx</code>	Sets minimum edge width. Once an edge is found, the search for the next edge starts $dx$ units beyond the found edge. Default $dx$ is 0.
<code>/P</code>	Output edge locations (see <b>Details</b> ) are set in terms of point number. If <code>/P</code> is omitted, edge locations are set in terms of X values.
<code>/Q</code>	Prevents results from being printed in history and prevents error if edge is not found.
<code>/R=(startX, endX)</code>	Specifies an X range of the wave to search. You may exchange $startX$ and $endX$ to reverse the search direction.
<code>/R=[startP, endP]</code>	Specifies a point range of the wave to search. You may exchange $startP$ and $endP$ to reverse the search direction. If you specify the range as <code>/R=[startP]</code> then the end of the range is taken as the end of the wave. If <code>/R</code> is omitted, the entire wave is searched.
<code>/T=dx</code>	Forces search in two directions for a possibly more accurate result. $dx$ controls where the second search starts.

### Details

The `/B=box`, `/T=dx`, `/P` and `/Q` flags behave the same as for the **FindLevel** operation.

PulseStats considers a region of the input wave between two X locations, called  $startX$  and  $endX$ .  $startX$  and  $endX$  are set by the `/R=(startX, endX)` flag. If this flag is missing,  $startX$  and  $endX$  default to the start and end of the entire wave.

The  $startLevel$  and  $endLevel$  values define the base levels of the pulse. You can explicitly set these levels with the `/L=(startLevel, endLevel)` flag or you can let PulseStats find the base levels for you by using the `/A=n` flag. With this flag, PulseStats determines  $startLevel$  and  $endLevel$  by averaging  $n$  points centered at  $startX$  and at  $endX$ . In case 2, you must use `/L=(startLevel, endLevel)` since  $startLevel$  is not at point 0.

Given  $startLevel$  and  $endLevel$  and an  $f$  value (which you can set with the `/F=f` flag), PulseStats computes  $level1$ ,  $level2$  and  $level3$  which are always equal. With the default  $f$  value of 0.5,  $level1$  is midway between  $startLevel$  and  $endLevel$ .

With these levels defined, PulseStats searches the wave from  $startX$  to  $endX$  looking for one, two or three level crossings. PulseStats sets the following variables:

<code>V_flag</code>	0: All three level crossings were found. 1: One or two level crossings were found. 2: No level crossings were found.
<code>V_PulseLoc1</code>	X location where $level1$ was found.
<code>V_PulseLoc2</code>	X location where $level2$ was found.
<code>V_PulseLoc3</code>	X location where $level3$ was found.
<code>V_PulseLv10</code>	$startLevel$ value.
<code>V_PulseLv1123</code>	Level1 value that is the same as $level2$ and $level3$ .
<code>V_PulseLv14</code>	$endLevel$ value.
<code>V_PulseAmp4_0</code>	Pulse amplitude ( $endLevel - startLevel$ ).
<code>V_PulseWidth2_1</code>	Left pulse width (x distance between point 2 and point 1).
<code>V_PulseWidth3_2</code>	Right pulse width (x distance between point 3 and point 2).
<code>V_PulseWidth3_1</code>	Pulse period (x distance between point 3 and point 1).
<code>V_PulsePolarity</code>	Trend of the edge at point 1 (-1 if decreasing, +1 if increasing).

X locations and distances are in terms of the X scaling of the source wave, unless you use the `/P` flag in which case they are in terms of point number.

## PutScrapText

---

If any level crossings are missing then PulseStats sets the associated variables to NaN (Not a Number). If one crossing is missing, variables depending on point 3 are set to NaN. If two crossings are missing, variables depending on points 2 and 3 are set to NaN. If all crossings are missing, variables depending on points 1, 2, and 3 are set to NaN. You can use the numtype function to test a variable to see if it is NaN.

The PulseStats operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details.

### See Also

The **FindLevel** operation about the /B=box, /T=dx, /P and /Q flags, **EdgeStats** and the **numtype** function.

## PutScrapText

### **PutScrapText** *textStr*

The PutScrapText operation places *textStr* on the Clipboard (aka “scrap”). This text will be used when the user subsequently chooses Paste from the Edit menu.

### Details

All contents of the Clipboard (including pictures) are cleared before the text is placed there.

### Examples

Put two lines of text into the Clipboard:

```
String text = "This is the first line.\r\nAnd this is the second."
PutScrapText text
```

Empty the Clipboard:

```
PutScrapText ""
```

### See Also

The **GetScrapText** function and the **SavePICT** operation.

## q

### q

The q function returns the current column index of the destination wave when used in a multidimensional wave assignment statement. The corresponding scaled column index is available as the y function.

### Details

Unlike p, outside of a wave assignment statement, q does not act like a normal variable.

### See Also

**Waveform Arithmetic and Assignments** on page II-80.

For other dimensions, the **p**, **r**, and **s** functions.

For scaled dimension indices, the **x**, **y**, **z** and **t** functions.

## qcsr

### **qcsr**(*cursorName* [, *graphNameStr*])

The qcsr function can be used with cursors on images or waterfall plots to return the column number. It can also be used with free cursors to return the relative Y coordinate.

### Parameters

*cursorName* identifies the cursor, which can be cursor A through J.

*graphNameStr* specifies the graph window or subwindow.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

### See Also

The **Cursor** operation and the **CsrInfo**, **hcsr**, **pcsr**, **vcscr**, **xcscr**, and **zcscr** functions.

## Quit

**Quit** [ /N/Y ]

The Quit operation quits Igor Pro.

### Flags

/N           Quits without saving changes and without dialog.  
/Y           Saves current experiment before quitting without putting up dialog unless current experiment is "Untitled".

## r

### r

The r function returns the current layer index of the destination wave when used in a multidimensional wave assignment statement. The corresponding scaled layer index is available as the z function.

### Details

Unlike **p**, outside of a wave assignment statement, r does not act like a normal variable.

### See Also

**Waveform Arithmetic and Assignments** on page II-80. For other dimensions, the **p**, **q**, **s**, and **t** functions. For scaled dimension indices, the **x**, **y**, **z**, and **t** functions.

## r2polar

### r2polar(z)

The r2polar function returns a complex value in polar coordinates derived from the complex value *z*, which is assumed to be in rectangular coordinates. The magnitude is stored in the real part and the angle (in radians) is stored in the imaginary part of the returned complex value.

### Examples

Assume waveIn and waveOut are complex.

```
waveOut= r2polar(waveIn)
```

sets each point of waveOut to the polar coordinates derived from the real and imaginary parts of waveIn.

You may get unexpected results if the number of points in waveIn differs from the number of points in waveOut.

### See Also

The functions **cmplx**, **conj**, **imag**, **p2rect**, and **real**.

## RatioFromNumber

**RatioFromNumber** [ *flags* ] *num*

The RatioFromNumber operation computes two integers whose ratio is equal to  $num \pm maxError$  (/MERR flag). The ratio is returned in V\_numerator and V\_denominator.

### Parameters

*num* is the number to approximate by V\_numerator/V\_denominator.

### Flags

/MERR=*maxError*       Specifies the maximum tolerable error. The computed ratio differs from *num* by no more than *maxError* (default value is  $num*1e-6$ ).  
*maxError* must be a value between 0 and *num*. See Details about setting *maxError* to 0.  
/MITS = *maxIterations*   Keeps returned values small by specifying a small number for *maxIterations*.  
*maxIterations* must be a value between 1 and 32767 (default is 100).  
/V[=*v*]               Prints output variables to history.  
*v*=1:       Prints variables (same as /V).  
*v*=0:       Nothing printed (same as no /V).

### Details

Setting /MERR = 0 computes a maximally accurate ratio. The returned values can be surprisingly large:

## ReadVariables

---

```
·RatioFromNumber/V/MERR=0 (1/1666)
  V_numerator= 4398046511104; V_denominator= 7.3271454874993e+15;
  ratio= 0.00060024009603842; V_difference= 0;
```

Using the default /MERR returns the expected 1 and 1666. The difference is attributable to floating-point roundoff errors.

The ratio is computed by continued fraction expansion and recurrence relations for the convergents and checking  $num - (V\_numerator/V\_denominator)$  against /MERR.

RatioFromNumber sets the following output variables:

V\_difference     V\_numerator/V\_denominator - num (positive if the approximation is too big).

V\_flag            0: V\_difference less than or equal to /MERR.

                  1: V\_difference greater than /MERR.

V\_numerator, V\_denominator

                  Values for the numerator and denominator. The ratio of V\_numerator/V\_denominator approximates num.

### Examples

```
·RatioFromNumber/V pi
  V_numerator= 355; V_denominator= 113; ratio= 3.141592920354;
  V_difference= 2.6676418940497e-07;
```

```
·RatioFromNumber/V/MITS=2 pi
  V_numerator= 22; V_denominator= 7; ratio= 3.1428571428571;
  V_difference= 0.0012644892673497;
```

### See Also

The gcd and trunc functions.

## ReadVariables

### ReadVariables

The ReadVariables operation reads variables into an experiment.

ReadVariables is used automatically when you open an experiment. You need not invoke it.

## real

### real(z)

The real function returns the real component of the complex value z.

### See Also

The functions **cmplx**, **conj**, **imag**, **p2rect**, and **r2polar**.

## Redimension

**Redimension** [*flags*] *waveName* [, *waveName*]...

The Redimension operation remakes the named waves, preserving their contents as much as possible.

### Flags

/B                Converts waves to 8-bit signed integer or unsigned integer if /U is present.

/C                Converts real waves to complex.

/D                Converts single precision waves to double precision.

/E=e             e=0:     No special action (default).

                  e=1:     Force reshape without converting or moving data.

                  e=2:     Perform endian swap. (See **FBinRead** for a discussion of endian byte ordering.)

/I                Converts waves to 32-bit signed integer or unsigned integer if /U is present.

/N=n             n is the new number of points each wave will have. Multidimensional waves are converted to 1 dimension.

/N=(n1, n2, n3, n4)

n1, n2, n3, n4 specify the number of rows, columns, layers, and chunks each wave will have.

Trailing zeros can be omitted (e.g., /N=(n1, n2, 0, 0) can be abbreviated as /N=(n1, n2)). If any dimension size is to remain unchanged, pass -1 for that dimension.

/R	Converts complex waves to real by discarding the imaginary part.
/S	Converts double precision waves to single precision.
/U	Converts integer waves to unsigned.
/W	Converts waves to 16-bit integer (unsigned integer if /U is present).

As a replacement for the above number type flags you can use `/Y=numType` to set the number type as an integer code. See the **WaveType** function for code values. Do not use `/Y` in combination with other type flags. This technique cannot be used to change the number type without changing the real/complex setting.

### Details

The waves must already exist. New points in waves that are extended are zeroed.

In general, Redimension does not move data from one dimension to another. For instance, if you have a 6x6 matrix wave, and you would like it to be 3x12, the rows have been shortened and the data for the last three rows is lost.

As a special case, if converting to or from a 1D wave, Redimension will leave the data in place while changing the dimensionality of the wave. For example, you can use Redimension to convert a 36-element 1D wave into a 6x6 matrix in which the elements in the first column (column 0) are the first 6 elements of the 1D wave, the elements of the second column are the next 6, etc. When redimensioning from a 1D wave, columns are filled first, then layers, followed by chunks.

### Examples

Reshaping a 1D wave having 4 elements to make a 2x2 matrix:

Make/N=4 vector=x

Redimension/N=(2,2) vector

### See Also

Lists of Values on page II-82; the **DeletePoints** and **Make** operations.

## Remove

### Remove

When interpreting a command, Igor treats the Remove operation as **RemoveFromGraph**, **RemoveFromTable**, or **RemoveFromLayout**, depending on the target window. This does not work when executing a user-defined function. Therefore, we recommend that you use **RemoveFromGraph**, **RemoveFromTable**, or **RemoveLayoutObjects** rather than Remove.

## RemoveByKey

**RemoveByKey(keyStr, kwListStr [, keySepStr [, listSepStr [, matchCase]])**

The RemoveByKey function returns *kwListStr* after removing the keyword-value pair specified by *keyStr*. *kwListStr* should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for *keySepStr* and *listSepStr*.

Use RemoveByKey to remove information from a string containing a "key1:value1;key2:value2;" or "key1=value1,key2=value2," style list such as those returned by functions like **AxisInfo** or **TraceInfo**.

If *keyStr* is not found then *kwListStr* is returned unchanged.

*keySepStr*, *listSepStr*, and *matchCase* are optional; their defaults are ":", ";", and 0 respectively.

### Details

*keyStr* is limited to 255 characters.

*kwListStr* is searched for an instance of the key string bound by *listSepStr* on the left and a *keySepStr* on the right. The key, the *keySepStr*, and the text up to and including the next *listSepStr* (if any) are removed from the returned string.

## RemoveContour

---

If the resulting string contains only *listSepStr* characters, then an empty string ("") is returned.

*kwListStr* is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *keySepStr* and *listSepStr* are always case-sensitive. Searches for *keyStr* in *kwListStr* are usually case-insensitive. Setting the optional *matchCase* parameter to 1 makes the comparisons case sensitive.

Only the first characters of *keySepStr* and *listSepStr* are used.

If *listSepStr* is specified, then *keySepStr* must also be specified. If *matchCase* is specified, *keySepStr* and *listSepStr* must be specified.

### Examples

```
Print RemoveByKey("AKEY", "AKEY:123;BKEY:val") // prints "BKEY:val"
Print RemoveByKey("AKEY", "akey=1;BK=b;", "=") // prints "BK:b;"
Print RemoveByKey("AKEY", "AKEY=1,BK=b;", "=", ",") // prints "BK:b,"
Print RemoveByKey("ckey", "CKEY:1;BKEY:2") // prints "BKEY:2"
Print RemoveByKey("ckey", "CKEY:1;BKEY:2", ":", ";", 1) // prints "AKEY:1;BKEY:2"
```

### See Also

The **NumberByKey**, **StringByKey**, **ReplaceNumberByKey**, **ReplaceStringByKey**, **ItemsInList**, **AxisInfo**, **IgorInfo**, **SetWindow**, and **TraceInfo** functions.

## RemoveContour

**RemoveContour** [*/W=winName*] *contourInstanceName* [, *contourInstanceName*]...

The RemoveContour operation removes the traces, and releases memory associated with the contour plot of *contourInstanceName* in the target or named graph.

### Parameters

*contourInstanceName* is usually simply the name of a wave. More precisely, *contourInstanceName* is a wave name, optionally followed by the # character and an instance number to identify which contour plot of a given wave is to be removed.

### Flags

*/W=winName* Removes contours from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.  
When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

### Details

If the axes used by the contour plot are no longer in use, they will also be removed.

An contour instance name in a string can be used with the \$ operator to specify *imageInstance*.

### Examples

```
Display;AppendMatrixContour zw //new graph, contour of zw matrix
AppendMatrixContour zw //two contours of zw
RemoveContour zw#1 //remove the second contour
```

### See Also

The **AppendMatrixContour** and **AppendXYZContour** operations.

## RemoveEnding

**RemoveEnding**(*str* [, *endingStr*])

The RemoveEnding function removes one character from the end of *str*, or it removes the *endingStr* from the end of *str*.

*endingStr* is optional. If missing, one character is removed from the end of *str*.

### Details

*endingStr* is compared to the end of *str* using a case insensitive comparison (such as *cmpstr* uses). If the end of *str* does not match *endingStr*, the unaltered *str* is returned.

**Examples**

```
Print RemoveEnding("123")           // prints "12"
Print RemoveEnding("no semi" , ";") // prints "no semi"
Print RemoveEnding("trailing semi;" , ";") // prints "trailing semi"
Print RemoveEnding("file.txt" , ".TXT") // prints "file"
```

**See Also**

The `cmpstr` and `ParseFilePath` functions.

**RemoveFromGraph**

**RemoveFromGraph** [/W=*winName*/Z] *traceName* [, *traceName*]...

The RemoveFromGraph operation removes the specified wave traces from the target or named graph. A trace is a representation of the data in a wave, usually connected line segments.

**Parameters**

*traceName* is usually the name of a wave.

More precisely, *traceName* is a wave name, optionally followed by the # character and an instance number. It is also referred to as a "trace". See **Examples**.

**Flags**

/W=*winName*      Removes traces from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.  
When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

/Z                Suppresses errors if specified trace or image is not on the graph.

**Details**

Up to 100 *traceNames* may be specified, subject to the 400 character command limit.

If the axes used by the given trace are not in use after removing the trace, they will also be removed.

A string containing a trace name can be used with the \$ operator to specify *traceName*.

Note that removing all the contour traces from a contour plot is not the same as removing the contour plot itself. Use the **RemoveContour** operation.

**Examples**

The command:

```
Display myWave,myWave;Modify mode(myWave#1)=6
```

appends two instances of myWave to the graph. The first/backmost instance of myWave is instance 0, and its trace name is just myWave as a synonym for myWave#0. The second or frontmost instance of myWave is myWave#1 and it is displayed with the cityscape mode.

To remove the second instance from the graph requires the command:

```
RemoveFromGraph myWave#1
```

or

```
String MyTraceName="myWave#1"
RemoveFromGraph $MyTraceName
```

**RemoveFromLayout**

**RemoveFromLayout** *objectSpec* [, *objectSpec*]...

Deprecated — use **RemoveLayoutObjects**.

The RemoveFromLayout operation removes the specified objects from the top layout.

**Parameters**

*objectSpec* is either an object name (e.g., Graph0) or an *objectName* with an instance (e.g., Graph0#1). An instance is needed only if the same object appears in the layout more than one time. Graph0 is equivalent to Graph0#0 and Graph0#1 refers to the second instance of Graph0 in the layout.

**See Also**

The **RemoveLayoutObjects** operation.

### RemoveFromList

**RemoveFromList**(*itemOrListStr*, *listStr* [, *listSepStr* [, *matchCase*]])

The RemoveFromList function returns *listStr* after removing the item or items specified by *itemOrListStr*. *listStr* should contain items separated by the *listSepStr* character, such as "abc;def;".

If *itemOrListStr* contains multiple items, they should be separated by the *listSepStr* character, too.

Use RemoveFromList to remove item(s) from a string containing a list of items separated by a single character, such as those returned by functions like **TraceNameList** or **AnnotationList**, or a line from a delimited text file.

If all items in *itemOrListStr* are not found or if any of the arguments is "" then *listStr* is returned unchanged (unless *listStr* contains only list separators, in which case the empty string is returned).

*listSepStr* and *matchCase* are optional; their defaults are ";" and 1 respectively.

#### Details

*itemStr* may have any length.

*listStr* is searched for an instance of the item string(s) bound by *listSepStr* on the left and right. The item and any trailing *listSepStr* (if any) are removed from the returned string.

If the resulting string contains only *listSepStr* characters, then an empty string ("") is returned.

*listStr* is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *listSepStr* are case-sensitive. Searches for *items* in *itemOrListStr* are usually case-sensitive. Setting the optional *matchCase* parameter to 0 makes the comparisons case insensitive.

Only the first character of *listSepStr* is used.

If *matchCase* is specified, then *listSepStr* must also be specified.

#### Examples

```
Print RemoveFromList("wave1", "wave0;wave1;")           // prints "wave0;"
Print RemoveFromList("wave1", ";wave1;;;")             // prints ""
Print RemoveFromList("KEY=joy", "AX=3,KEY=joy", ",")    // prints "AX=3,"
Print RemoveFromList("fred", "fred\twilma", "\t")      // prints "wilma"
Print RemoveFromList("fred;barney", "fred;wilma;barney") // prints "wilma;"
Print "X"+RemoveFromList("",";";";")+"Y"              // prints "XY"
Print RemoveFromList("FRED", "fred;wilma")             // prints "fred;wilma"
Print RemoveFromList("FRED", "fred;wilma", ";", 0)     // prints "wilma"
```

#### See Also

The **FindListItem**, **FunctionList**, **ItemsInList**, **RemoveByKey**, **RemoveListItem**, **StringFromList**, **StringList**, **TraceNameList**, **UpperStr**, **VariableList**, and **WaveList** functions.

### RemoveFromTable

**RemoveFromTable** [/W=*winName*] *columnSpec* [, *columnSpec*]..

The RemoveFromTable operation removes the specified columns from the top table.

#### Parameters

*columnSpecs* are the same as for the **Edit** operation; usually they are just the names of waves.

#### Flags

/W=*winName* Removes columns from the named table window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

#### See Also

**Edit** about *columnSpecs*, and **AppendToTable**.

## RemoveImage

**RemoveImage** [/W=*winName*/Z] *imageInstance* [, *imageInstance*]...

The RemoveImage operation removes the given image from the target or named graph.

### Parameters

*imageInstance* is usually simply the name of a wave. More precisely, *imageInstance* is a wave name, optionally followed by the # character and an instance number to identify which image of a given wave is to be removed.

### Flags

*/W=winName* Removes an image from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. Must be the first flag specified when used in a Proc or Macro or on the command line.  
When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

*/Z* Suppresses errors if specified image is not on the graph.

### Details

If the axes used by the given image are not in use after removing the image, they will also be removed.

An image name in a string can be used with the \$ operator to specify *imageInstance*.

### See Also

The **AppendImage** operation.

## RemoveLayoutObjects

**RemoveLayoutObjects** [/W=*winName*/Z] *objectSpec* [, *objectSpec*]

The RemoveLayoutObjects operation removes the specified object or objects from the top page layout, or from the layout specified by the */W* flag.

Unlike the RemoveFromLayout operation, RemoveLayoutObjects can be used in user-defined functions. Therefore, RemoveLayoutObjects should be used in new programming.

### Parameters

*objectSpec* is either an object name (e.g., Graph0) or an *objectName* with an instance (e.g., Graph0#1). An instance is needed only if the same object appears in the layout more than one time. Graph0 is equivalent to Graph0#0 and Graph0#1 refers to the second instance of Graph0 in the layout.

### Flags

*/W=winName* *winName* is the name of the page layout window from which the object is to be removed. If */W* is omitted or if *winName* is \$ " ", the top page layout is used.

*/Z* Does not report errors if the specified layout object does not exist.

### See Also

**NewLayout**, **AppendLayoutObject** and **ModifyLayout**.

## RemoveListItem

**RemoveListItem**(*itemNum*, *listStr* [, *listSepStr*])

The RemoveListItem function returns *listStr* after removing the item specified by the list index *itemNum*. *listStr* should contain items separated by the *listSepStr* character, such as "abc;def;". *itemNum* should be a number between 0 (the index of the first item in a list) and `ItemsInList(listStr) - 1`.

RemoveListItem removes an item from a string containing a list of items separated by a single character, such as those returned by functions like **TraceNameList** or **AnnotationList**, or a line from a delimited text file.

*listSepStr* is optional. If missing, *listSepStr* is presumed to be ";".

### Details

RemoveListItem differs from **RemoveFromList** in that RemoveListItem specifies the item to be removed by index and removes only that item, while RemoveFromList specifies the item to be removed by value, and removes all matching items.

If *itemNum* less than 0 or greater than `ItemsInList(listStr) - 1`, or if *listSepStr* is " " then *listStr* is returned unchanged (unless *listStr* contains only list separators, in which case the empty string is returned).

## RemovePath

---

If the resulting string contains only *listSepStr* characters, then an empty string ("") is returned.

*listStr* is treated as if it ends with a *listSepStr* even if it doesn't. Searches for *itemStr* and *listSepStr* are case-sensitive.

Only the first character of *listSepStr* is used.

### Examples

```
Print RemoveListItem(1, "wave0;wave1;w2;")           // prints "wave0;w2;"
Print RemoveListItem(0, "wave1;;;")                 // prints ""
Print RemoveListItem(1, "AX=3,KEY=joy", ",",")       // prints "AX=3,"
Print RemoveListItem(1, "fred\twilma", "\t")         // prints "fred\t"
```

### See Also

The **AddListItem**, **FindListItem**, **FunctionList**, **ItemsInList**, **RemoveByKey**, **RemoveFromList**, **StringFromList**, **StringList**, **TraceNameList**, **VariableList**, **WaveList**, and **WhichListItem** functions.

## RemovePath

**RemovePath** [/A/Z] *pathName*

The RemovePath operation removes a path from the list of symbolic paths. RemovePath is an old name for the new **KillPath** operation, which we recommend you use instead.

## Rename

**Rename** *oldName*, *newName*

The Rename operation renames waves, strings, or numeric variables from *oldName* to *newName*.

### Parameters

*oldName* may be a simple object name or a data folder path and name. *newName* must be a simple object name.

### Details

You can not rename an object using a name that already exists. The following will result in an error:

```
Make wave0, wave1
// Rename wave0 and overwrite wave1.
Rename wave0, wave1           // This will not work.
```

However, you can achieve the desired effect as follows:

```
Make wave0, wave1
Duplicate/O wave0, wave1; KillWaves wave0
```

### See Also

The **Duplicate** operation.

## RenameDataFolder

**RenameDataFolder** *sourceDataFolderSpec*, *newName*

The RenameDataFolder operation changes the name of the source data folder to the new name.

*sourceDataFolderSpec* can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

*newName* is just the new name for the data folder, without any path.

### Details

RenameDataFolder generates an error if the new name is already in use as a data folder contained within the source data folder.

### Examples

```
RenameDataFolder root:foo,foo2           // Change name of foo to foo2
```

### See Also

Chapter II-8, **Data Folders**.

## RenamePath

**RenamePath** *oldName*, *newName*

The RenamePath operation renames an existing symbolic path from *oldName* to *newName*.

**See Also**

Symbolic Paths on page II-30

## RenamePICT

**RenamePICT** *oldName*, *newName*

The RenamePICT operation renames an existing picture to from *oldName* to *newName*.

**See Also**

Pictures on page III-405.

## RenameWindow

**RenameWindow** *oldName*, *newName*

The RenameWindow operation renames an existing window or subwindow from *oldName* to *newName*.

**Parameters**

*oldName* is the name of an existing window or subwindow.

When identifying a subwindow with *oldName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**See Also**

The DoWindow operation.

## ReorderTraces

**ReorderTraces** [/W=*winName*] *anchortrace*, {*traceA*, *traceB*, ...}

The ReorderTraces operation changes the ordering of graph traces to that specified in the braces.

**Flags**

/W=*winName* Reorders traces in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**Details**

Igor keeps a list of traces in a graph and draws the traces in the listed order. The first trace drawn is consequently at the bottom. All other traces are drawn on top of it. The last trace is the top one; no other trace obscures it.

ReorderTraces works by removing the traces in the braces from the list and then reinserting them at the location specified by *anchortrace*. If *anchortrace* is not in the braces, the traces in braces are placed before *anchortrace*.

If the list of traces is A, B, C, D, E, F, G and you execute the command

```
ReorderTraces F, {B,C}
```

traces B and C are placed just before F: A, D, E, B, C, F, G.

The result of

```
ReorderTraces E, {D,E,C}
```

is to reorder C, D and E and put them where E was. Starting from the initial ordering results in A, B, D, E, C, F, G.

ReorderTraces generates an error if the same trace is in the list twice.

### ReplaceNumberByKey

**ReplaceNumberByKey**(*keyStr*, *kwListStr*, *newNum* [, *keySepStr* [, *listSepStr* [, *case*]]])

The `ReplaceNumberByKey` function returns *kwListStr* after replacing the numeric value of the keyword-value pair specified by *keyStr*. *kwListStr* should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for *keySepStr* and *listSepStr*.

Use `ReplaceNumberByKey` to add or modify numeric information in a string containing a "key1:value1;key2:value2;" style list such as those returned by functions like `AxisInfo` or `TraceInfo`. If *keyStr* is not found in *kwListStr*, then the key and the value are appended to the end of the returned string. *keySepStr*, *listSepStr*, and *case* are optional; their defaults are ":", ";", and 0 respectively.

#### Details

The actual string appended is:

```
[listSepStr] keyStr keySepStr newNum listSepStr
```

The optional leading list separator *listSepStr* is added only if *kwListStr* does not already end with a list separator. *keyStr* is limited to 255 characters.

*kwListStr* is searched for an instance of the key string bound by *listSepStr* on the left and a *keySepStr* on the right. The text up to the next ";" is replaced by *newNum* after conversion to text using the `%.15g` format (see `printf` for format conversion specifications).

*kwListStr* is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *keySepStr* and *listSepStr* are always case-sensitive. Searches for *keyStr* in *kwListStr* are usually case-insensitive. Setting the optional *case* parameter to 0 makes the comparisons case sensitive.

Only the first characters of *keySepStr* and *listSepStr* are used.

If *listSepStr* is specified, then *keySepStr* must also be specified. If *case* is specified, *keySepStr* and *listSepStr* must be specified.

#### Examples

```
Print ReplaceNumberByKey("K1", "K1:7;", 4) // prints "K1:4;"
Print ReplaceNumberByKey("k2", "K2=8;", 5, "=") // prints "K2=5;"
Print ReplaceNumberByKey("K3", "K3:9,", 6, ":", ",") // prints "K3:6,"
Print ReplaceNumberByKey("k3", "K0:9", 6, ":", ",") // prints "K0:9,k3:6,"
Print ReplaceNumberByKey("k3", "K3:9,", 6, ":", ",") // prints "K3:9,"
Print ReplaceNumberByKey("k3", "K3:9,", 6, ":", ",", 1) // prints "k3:9,k3:6,"
```

#### See Also

The `ReplaceStringByKey`, `NumberByKey`, `StringByKey`, `RemoveByKey`, `ItemsInList`, `AxisInfo`, `IgorInfo`, `SetWindow`, and `TraceInfo` functions.

### ReplaceString

**ReplaceString**(*replaceThisStr*, *inStr*, *withThisStr* [, *caseSense* [, *maxReplace*]])

The `ReplaceString` function returns *inStr* after replacing any instance of *replaceThisStr* with *withThisStr*.

The comparison of *replaceThisStr* to the contents of *inStr* is case-insensitive. Setting the optional *caseSense* parameter to nonzero makes the comparison case-sensitive.

Usually all instances of *replaceThisStr* are replaced. Setting the optional *maxReplace* parameter limits the replacements to that number.

#### Details

If *replaceThisStr* is not found, *inStr* is returned unchanged.

If *maxReplace* is less than 1, then no replacements are made. Setting *maxReplace* = `Inf` is the same as omitting it.

#### Examples

```
Print ReplaceString("hello", "say hello", "goodbye") // prints "say goodbye"
Print ReplaceString("\r\n", "line1\r\nline2", "") // prints "line1line2"
Print ReplaceString("A", "an Ack-Ack", "a", 1) // prints "an ack-ack"
```

```
Print ReplaceString("A", "an Ack-Ack", "a", 1, 1) // prints "an ack-Ack"
Print ReplaceString("", "input", "whatever") // prints "input" (no change)
```

### See Also

The **ReplaceStringByKey**, **cmpstr**, **stringmatch**, and **strsearch** functions.

## ReplaceStringByKey

```
ReplaceStringByKey(keyStr, kwListStr, newTextStr [, keySepStr
[, listSepStr [, matchCase]])
```

The **ReplaceStringByKey** function returns *kwListStr* after replacing the text value of the keyword-value pair specified by *keyStr*. *kwListStr* should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for *keySepStr* and *listSepStr*.

Use **ReplaceStringByKey** to add or modify text information in a string containing a "key1:value1;key2:value2;" style list such as those returned by functions like **AxisInfo** or **TraceInfo**.

If *keyStr* is not found in *kwListStr*, then the key and the value are appended to the end of the returned string.

*keySepStr*, *listSepStr*, and *matchCase* are optional; their defaults are ":", ";", and 0 respectively.

### Details

The actual string appended is:

```
[listSepStr] keyStr keySepStr newTextStr listSepStr
```

The optional leading list separator *listSepStr* is added only if *kwListStr* does not already end with a list separator.

*keyStr* is limited to 255 characters.

*kwListStr* is searched for an instance of the key string bound by a ";" on the left and a ":" on the right. The text up to the next ";" is replaced by *newTextStr*.

If *newTextStr* is "", any existing value is deleted, but the key, the key separator, and the list separator are retained. To remove a keyword-value pair, use the **RemoveByKey** function.

*kwListStr* is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *keySepStr* and *listSepStr* are always case-sensitive. Searches for *keyStr* in *kwListStr* are case-insensitive. Setting the optional *matchCase* parameter to 1 makes the comparisons case-sensitive.

Only the first characters of *keySepStr* and *listSepStr* are used.

If *listSepStr* is specified, then *keySepStr* must also be specified. If *matchCase* is specified, *keySepStr* and *listSepStr* must be specified.

### Examples

```
Print ReplaceStringByKey("KY", "KY:a;KZ:c", "b") // prints "KY:b;KZ:c"
Print ReplaceStringByKey("KY", "ky=a;", "b", "=") // prints "ky=b;"
Print ReplaceStringByKey("KY", "KY:a,", "b", ":", ",") // prints "KY:b,"
Print ReplaceStringByKey("ky", "ZZ:a,", "b", ":", ",") // prints "ZZ:a,ky:b,"
Print ReplaceStringByKey("kz", "KZ:a,", "b", ":", ",") // prints "KZ:b,"
Print ReplaceStringByKey("kz", "KZ:a,", "b", ":", ",", 1) // prints "KZ:a,kz:b,"
```

### See Also

The **ReplaceString**, **ReplaceNumberByKey**, **NumberByKey**, **StringByKey**, **ItemsInList**, **RemoveByKey**, **AxisInfo**, **IgorInfo**, **SetWindow**, and **TraceInfo** functions.

## ReplaceText

```
ReplaceText [/W=winName/N=name] textStr
```

The **ReplaceText** operation replaces the text in the most recently created or changed annotation or in the annotation specified by /W=*winName* and /N=*name*.

### Parameters

*textStr* can contain escape codes to control font, font size and other stylistic variations.

If the annotation is a color scale, this command replaces the text of the color scale's main axis label.

### Flags

/N=*name* Replaces the text of the named tag or textbox.

## ReplaceWave

---

*/W=winName* Replaces text in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.  
When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

### See Also

See the **Tag** and **TextBox** operations for details about the *textStr* parameter.

The **ColorScale** operation.

## ReplaceWave

**ReplaceWave** [*/W=winName*] **allinCDF**

**ReplaceWave** [*/X/W=winName*] **trace=traceName, waveName**

**ReplaceWave** [*/X/Y/W=winName*] **image=imageName, waveName**

**ReplaceWave** [*/X/Y/W=winName*] **contour=contourName, waveName**

The ReplaceWave operation replaces waves displayed in a graph with other waves. The waves to be replaced, and the replacement waves are chosen by the flags, the keyword and the wave names on the command line.

### Flags

*/W=winName* Replaces the wave in the named graph window or subwindow. When omitted, action will affect the active window or subwindow.  
When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

*/X* Replaces the wave defining the X data spacing.

*/Y* Replaces the wave defining the Y data spacing.

### Keywords

*allinCDF* Searches the current data folder for waves with the same names as waves used in the graph. If found and if the waves are of the correct type, they replace the existing waves. Thus, if you have several data folders with identically-named waves containing data from different experimental runs, you can browse through the runs by moving from one data folder to another, using **ReplaceWave allinCDF** to update the graph.

*contour=contourName* Replaces the wave supplying the Z data for *contourName*. If */X* or */Y* is used, replaces the wave used to set the X or Y data spacing (if the Z data are in a matrix) or the wave used to supply the X or Y positions if XYZ triplets were specified with three separate waves.

*image=imageName* Replaces the wave supplying the Z data for *imageName*. If */X* or */Y* is used, replaces the wave used to set the X or Y data spacing.

*trace=traceName* Replaces the wave associated with *traceName*. With the */X* flag, *waveName* will replace the X wave associated with *traceName*, otherwise it will replace the Y wave. Note that *traceName* is derived from the Y wave name; if you created a graph using **Display jack vs sam**, you would use **ReplaceWave/X trace=jack, newsam** to replace the X wave.

### Details

Waves are replaced in the graph specified by */W=winName* otherwise waves are replaced in the top graph.

Updating a contour plot in response to replacing a wave can be time-consuming. If you must replace more than one wave, put all the commands separated by semicolons on a single line. In a macro, use

**DelayUpdate** to prevent updates between command lines.

When using the *allinCDF* keyword, **ReplaceWave** cannot find waves buried in dynamic annotation text (for instance, using the `\{}` syntax in an annotation). **ReplaceWave** will not replace waves used for error bars, either.

Subsets of data, including individual rows or columns from a matrix, may be specified using **Subrange Display Syntax** on page II-267.

## Examples

Make XY plot, then replace the waves:

```

Make fred=x, sam=log(x)
Display fred vs sam
Make fred2=2*x, sam2=ln(x)
ReplaceWave/X trace=fred, sam2
ReplaceWave trace=fred, fred2           // trace is now named fred2

```

Make contour plot with XYZ triplet waves, then replace the waves. Note the DelayUpdate commands after the first two ReplaceWave commands:

```

Make/N=100 junkx, junky, junkz           // Waves for XYZ triplets
junkx=trunc(x/10)                        // X wave for XYZ triplets
junky=mod(x,10)                          // Y wave for XYZ triplets
junkz=sin(junkx[p])*cos(junky[p])        // Z wave for XYZ triplets
Display; AppendXYZContour junkz vs {junkx, junky} // Make contour plot
Make/O/N=150 junkx2, junky2, junkz2      // Make replacement waves
junkx2=trunc(x/15)
junky2=mod(x,15)
junkz2=sin(junkx2[p])*cos(junky2[p])
ReplaceWave/X contour=junkz, junkx2; DelayUpdate
ReplaceWave/Y contour=junkz, junky2; DelayUpdate
ReplaceWave contour=junkz, junkz2

```

This example is suitable for copying all the lines and pasting into the command line, or for use in a macro. If you are typing on the command line, you would want to put the ReplaceWave commands all on one line:

```

ReplaceWave/X contour=junkz, junkx2; ReplaceWave/Y contour=...

```

## Resample

**Resample** [*flags*] *waveName* [, *waveName*]...

The Resample operation resamples *waveName* by interpolating or up-sampling (set by /UP=*upSample*), lowpass filtering, and decimating or down-sampling (set by /DOWN=*downSample*).

Lowpass filtering is specified with /N and /WINF or with /COEF=*coefsWaveName*.

The sampling frequency (1/DimDelta) of a resampled output wave *waveName* is changed by the ratio of *downSample* / *upSample*. For example, if *upSample*=4 and *downSample*=3, then the final sampling rate is 3/4 of the original value.

Straight interpolation can be accomplished by setting *upSample* to the interpolation factor and *downSample*=1, in which case the sample rate is multiplied by *upSample*. Deltax(*waveName*) will be proportionally smaller.

For decimation only, set *upSample*=1 and *downSample* to the decimation factor. The sample rate is divided by *downSample*, and deltax(*waveName*) will be proportionally larger.

Use **RatioFromNumber** to choose appropriate values for *upSample* and *downSample*, or use /SAME=*sWaveName* or /RATE=*sampRate*. See **Resampling Rates Example** for details.

When using /COEF=*coefsWaveName*, the filter coefficients should implement a low-pass filter appropriate for the *upSample* and *downSample* values or aliasing (filtering errors) will result. See **Advanced Externally-Supplied Low Pass Filter Example** for details.

### Resampling Rates Flags

The *upSample* and *downSample* values define how much interpolation and decimation to perform. They can be set directly with /UP and /DOWN or indirectly with /SAME or /RATE

/DOWN=*downSample*

Down-samples or decimates the filtered result by this integer factor after up-sampling and lowpass filtering. The default is 1 (no down-sampling).

For example, /DOWN=3 places only every third value in the output wave.

Down-sampling divides the sampling rate of the filtered data by a factor of *downSample*. The DimDelta(*waveName*, *dim*) value is multiplied by the same factor.

/RATE=*sampRate*

Converts the output *waveName* to the specified sampling rate frequency (normally Hz).

The necessary *upSample* and *downSample* values for each *waveName* are computed internally as if you had executed:

```

RatioFromNumber (deltax(waveName)*sampRate)
upSample = v_numerator
downSample = v_denominator

```

/RATE returns *V\_numerator* and *V\_denominator* set to these automatically-determined values for the last *waveName*.

/SAME=*sWaveName*

Converts the output *waveName* to the same sampling rate as *sWaveName*,  $1/\text{DimDelta}(sWaveName, dim)$ . The necessary *upSample* and *downSample* values are computed internally as if you had executed:

```
Variable dd = DimDelta(waveName, dim)
RatioFromNumber dd/DimDelta(sWaveName, dim)
upSample = V_numerator
downSample = V_denominator
```

/SAME returns *V\_numerator* and *V\_denominator* set to these automatically-determined values for the last *waveName*.

/UP=*upSample*

Up-samples or interpolates the input by this integer factor. The default is 1 (no up-sampling).

For example, /UP=4 inserts three extra points between each input point (producing 4 times as many values) before the lowpass filtering and down-sampling occurs.

Up-sampling multiplies the sampling rate of the input data by a factor of *upSample*, though no additional signal information is created. The  $\text{DimDelta}(waveName, dim)$  value is divided by the same factor.

### Internal Sinc Reconstruction Filter Flags

If /COEF=*coefsWaveName* is not specified, Resample computes a windowed sinc filter from /N, /UP, and /WINF flag values.

If /COEF=*coefsWaveName* is specified, then *coefsWaveName* supplies the filter, and /N and /WINF are ignored. See **Externally-Supplied Low Pass Filter Flags**.

/COEF

Replaces the first *waveName* with coefficients generated by *upSample*, *numReconstructionSamples*, and *windowKindName*, a windowed sinc impulse response.

When resampling multiple *waveNames* with different filters (because /RATE or /SAME were specified and the multiple *waveNames* had different sampling rates), the filter used to resample the last *waveName* is returned.

/N=*numReconstructionSamples*

Specifies the number of input values used to create the up-sampled values (default is 21).

If even, *numReconstructionSamples* is rounded up to the next odd value.

The size of the computed filter is

$(numReconstructionSamples-1) * upSample + 1$ .

Bigger is better: 15 is usually on the low side for yielding reasonably accurate results, and although 101 will nearly always give very good results, it will be slow.

Use /COEF to output the impulse response, and the FFT to display the frequency response of the interpolator:

```
Make/O coefs
Resample/COEF/N=someNumber coefs
FFT/OUT=3/DEST=coefs_FFT coefs
Display coefs_FFT
```

Bigger is also slower: the filtering is computed in the time-domain, and execution time is linearly related to

$upSample / downSample * numReconstructionSamples$ .

/WINF=*windowKindName*

Applies the window, *windowKindName*, to the computed filter coefficients. If /WINF is omitted, the Hanning window is used. For no coefficient windowing, use /WINF=None, though this is discouraged.

Windows alter the frequency response of the filter in obvious and subtle ways, enhancing the stop-band rejection or steepening the transition region between passed and rejected frequencies. They matter less when *numReconstructionSamples* is large.

Choices for *windowKindName* are (see the FFT /WINF flag for details):

Bartlett, Blackman367, Blackman361, Blackman492, Blackman474, Cos1, Cos2, Cos3, Cos4, Hamming, Hanning, KaiserBessel20, KaiserBessel25, KaiserBessel30, Parzen, Poisson2, Poisson3, Poisson4, and Riemann.

### Externally-Supplied Low Pass Filter Flags

*/COEF =coefsWaveName*

Identifies the wave, *coefsWaveName*, containing filter coefficients that implement a low-pass filter with a cutoff frequency of the lesser of  $0.5/upSample$  and  $0.5/downSample$ , where 0.5 corresponds to the Nyquist frequency of the up-sampled data.

For example, if  $upSample=2$ , then the filter must contain the classic “half-band” filter, which stops the higher half of the frequencies and passes the lower half. If  $upSample=10$ , then the filter must pass only the lowest 1/10th of the frequencies.

For  $downSample > upSample$ , the low-pass filter’s cutoff frequency must be  $0.5/downSample$ . This prevents the decimation from introducing aliasing to the resampled data.

To avoid shifting the output with respect to the input, *coefsWaveName* must have an odd length with the “center” coefficient in the middle of the wave.

The length of *coefsWaveName* must be  $1+upSample*n$ , where  $n$  is any even integer.

**Note:** Instead of using  $/N=numReconstructionSamples$  with */COEF*,  $numReconstructionSamples$  is computed from  $upSample$  and the number of points in *coefsWaveName*:

$numReconstructionSamples=1+(numpts(coefsWaveName)-1)/upSample$ .

Coefficients are usually symmetrical about the middle point, but this is not enforced.

*coefsWaveName* must not be a destination *waveName*.

*coefsWaveName* must be single- or double-precision numeric and one-dimensional.

### Data Range Flags

*/DIM=d*

Specifies the wave dimension to resample.

For  $d=0, 1, \dots$ , resampling is along rows, columns, etc.

The default is */DIM=0*, which resamples each individual column (each one a channel, say left and right) in a multidimensional *waveName* where each row comprises all sound samples at a particular time.

To resample in multiple dimensions, execute the command once for each dimension. For example, use */DIM=0* followed by another command with */DIM=1* to resample a two-dimensional wave in each direction.

*/E=endEffect*

Determines how to handle the ends of the resampled wave(s) ( $w$ ) when fabricating missing neighbor values.

*endEffect=0*: Bounce method. Uses  $w[i]$  in place of the missing  $w[-i]$  and  $w[n-i]$  in place of the missing  $w[n+i]$ .

*endEffect=1*: Wrap method. Uses  $w[n-i]$  in place of the missing  $w[-i]$  and vice versa.

*endEffect=2*: Zero method (default). Uses 0 for any missing value.

*endEffect=3*: Fill method. Uses  $w[0]$  in place of the missing  $w[-i]$  and  $w[n]$  in place of the missing  $w[n+i]$ .

### Parameters

*waveName* may be one-dimensional or two-dimensional waves. Without */DIM*, resampling is done along the row (first) dimension. Each column is resampled as if it were a separate one-dimensional row. This allows multichannel audio to be resampled to another frequency.

If */DIM=1*, then resampling proceeds across all the columns of each row.

If */COEF* is specified without *coefsWaveName*, then the first *waveName* is overwritten by the filter coefficients instead of being resampled.

### Details

The filtering convolution is performed in the time-domain. That is, the FFT is not employed to filter the data. For this reason the coefficients length ( $/N$  or the length of *coefsWaveName*) should be small in comparison to the resampled waves.

## Resample

---

Resample assumes that the middle point of *coefsWaveName* corresponds to the delay=0 point. The “middle” point number =  $\text{trunc}(\text{numpts}(\text{coefsWaveName} - 1)/2)$ . *coefsWaveName* usually contains the two-sided impulse response of a filter, an odd number of points, and implements a low-pass filter whose cutoff frequency is the lesser of  $0.5/\text{upSample}$  and  $0.5/\text{downSample}$  (0.5 corresponds to the Nyquist frequency =  $1/2$  sampling frequency).

When /COEF creates a coefficients wave it sets the X scale deltax to 1 and alters the leftx value so that the zero-phase (center) coefficient is located at  $x=0$ .

### Simple Examples

Interpolation by factor of 4, default filter:

```
Resample/UP=4 data
```

Decimation by factor of 3, default filter:

```
Resample/DOWN=3 data
```

Match sampling rates, default filter:

```
Resample/SAME=dataAtDesiredRate dataAtWrongRate1, dataAtWrongRate2,...
```

Resample waves to 10 KHz sampling rate:

```
Resample/RATE=10e3 dataAtWrongRate1, dataAtWrongRate2,...
```

Interpolate an image by a factor of 2:

```
Resample/UP=2 image // default is /DIM=0, resample rows
Resample/UP=2/DIM=1 image // resample across columns
```

**Note:** Interpolating by a factor of two does not produce an image with twice as many rows and columns. The new number of rows =  $(\text{original rows} - 1) * \text{upSample} + 1$ , and a similar computation applies to columns.

### Resampling Rates Example

Suppose we have an audio wave sampled at 44,100 Hz and we wish to resample it to a higher 192,000 Hz frequency.

We can use /RATE= 192000 and let Resample determine the correct values (provided *waveName* has its X scaling set properly to reflect sampling at 44100 Hz), but let's compute *upSample* and *downSample* ourselves.

Because the sampling rate =  $1/\text{deltax}(\text{wave})$ , we can recast the /SAME formula to  $\text{RatioFromNumber}(\text{desiredSamplingRate}/\text{currentSamplingRate})$ :

```
·RatioFromNumber/V (192000 / 44100)
  V_numerator= 640; V_denominator= 147;
  ratio= 4.3537414965986;
  V_difference= 0;
```

Then *upSample*=640 and *downSample*=147.

The 44100 Hz input data will be interpolated by 640 to 28,224,000 Hz.

The result is low-pass filtered with a “cutoff frequency” of  $1/640$ th of the interpolated Nyquist frequency =  $(28224000/2)/640 = 22,050$  Hz, the same as the input signal's original Nyquist frequency.

The result will be decimated by 147 to 192,000 Hz, which is the desired output sampling frequency.

**Note:** If *downSample* had been greater than *upSample*, then the low-pass filter's cutoff frequency would have been  $1/\text{downSample}$ th of the interpolated Nyquist frequency =  $(28224000/2)/\text{downSample}$ . This prevents the decimation from introducing aliasing to the resampled data.

```
Resample/UP=640/DOWN=147 sound // convert 44.1 KHz to 192 KHz
```

### Advanced Externally-Supplied Low Pass Filter Example

You can generate an appropriate filter by executing commands like these:

```
// Compute a filter for after the input is upsampled
// to restore the frequency content to the original range.
Variable fc = min(0.5 / upSample, 0.5 * upSample / downSample)
// Transition width, small widths need big n
Variable tw= fc/10
// Set end of pass band
Variable f1= fc-tw/2
// Set start of stop band
Variable f2= fc+tw/2
// Use bigger values of n to make the filter smoother
```

```

Variable nReconstruct= 31
Variable n= (nReconstruct-1)*upSample+1           // odd = no phase shift
// Create a wave to hold the coefficients; it gets resized to n
Make/O/N=0 coefsWaveName
FilterFIR/COEF/LO={f1,f2,n} coefsWaveName

```

However, FilterFIR does not create windowed sinc lowpass filters that have the endearing property that the original input values are unaltered in the filtered output, though only if  $upSample > downSample$ . This is called a “Nyquist filter” or “Kth-band filter” in the literature.

If  $upSample > downSample$ , you can enforce the Nyquist criterion by “zeroizing” the designed filter by setting every  $upSample$ th value to 0 except the center one.

```

// coefsWaveName length must be 1+upSample*n, where n is any even integer
Function Zeroize(w, upSample)
    Wave w           // coefsWaveName
    Variable upSample // upSample value
    Variable n= DimSize(w,0)
    Variable centerP= floor((n-1)/2) // if n=101, centerP= 50
    Variable i
    for (i=0; i<n; i+=upSample)
        if( i != centerP )
            w[i] = 0
        endif
    endfor
End

```

Resample zeroizes the internally-generated low pass filter when  $upSample > downSample$ .

Additionally, the FilterFIR command generates a low-pass filter whose gain needs to be multiplied by  $upsample$ :  
 $coefsWaveName *= upSample$

When designing an externally supplied filter, you should also consider the filter’s “polyphase” nature;  $coefsWaveName$  is actually a set of  $upSample$  interleaved filters, each with its own response. It makes sense to adjust these filters to produce consistent responses. If you don’t, the results will contain ringing with a period of  $upSample / downSample$ . This is most apparent when  $downSample$  is 1.

Using the filter we’ve designed so far with  $upSample=4$ , here’s the output of a constant-input wave:

```

Make/O constantData= 1
Resample/COEF=coefsWaveName/UP=4 constantData

```

The graph shows that the filter response at 0 Hz for the first of 4 filters is 1.0010, the second and fourth filter’s responses are very close to 1.0, and the third filter’s response at 0 Hz is a little less than 1.0.

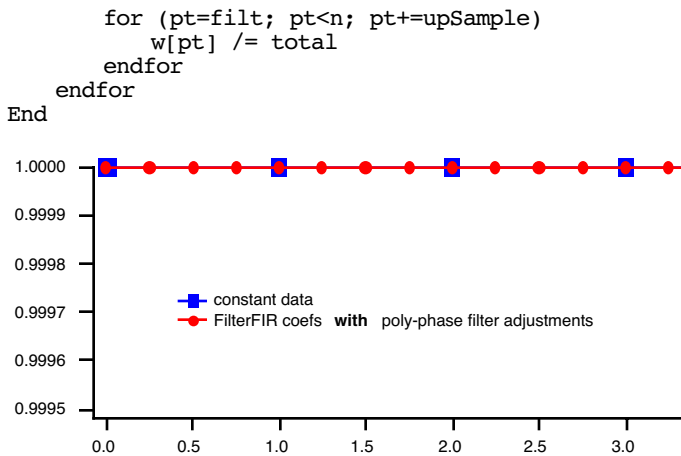

These variations can be eliminated by normalizing the sum of each polyphase filter to 1.0:

```

Function PolyphaseNormalize(w, upSample)
    Wave w           // coefsWaveName
    Variable upSample // upSample value
    Variable n= DimSize(w,0)
    Variable filt
    // for each filter (0..upSample-1)
    for (filt=0; filt<upSample; filt+=1)
        Variable total=0
        Variable pt
        // compute total for this filter
        for (pt=filt; pt<n; pt+=upSample)
            total += w[pt]
        endfor
        // divide by total to normalize total to 1
    endfor
End

```

## ResumeUpdate

Now the filter is ready to be used to filter data:

```
Resample/COEF=coefsWaveName/UP=(upSample)/DOWN=(downSample) dataWave
```

You can see that designing an externally-supplied lowpass filter is much more complicated than using the internal sinc reconstruction filter, which does all this zeroizing, scaling, and polyphase normalization for you.

## ResumeUpdate

### ResumeUpdate

The **ResumeUpdate** operation cancels the corresponding **PauseUpdate**.

This operation is of use in macros. It is not allowed from the command line. It is allowed but has no effect in user-defined functions. During execution of a user-defined function, windows update only when you explicitly call the **DoUpdate** operation.

### See Also

The **DelayUpdate**, **DoUpdate**, and **PauseUpdate** operations.

## return

### return [ *expression* ]

The return flow control keyword immediately stops execution of the current procedure. If called by another procedure, it returns *expression* and control to the calling procedure.

Functions can return only a single value directly to the calling procedure with a return statement. The return value must be compatible with the function type. A function may contain any number of return statements; only the first one encountered during procedure execution is evaluated.

A macro has no return value, so return simply quits the macro.

### See Also

The **Return Statement** on page IV-30.

## Reverse

```
Reverse [ type flags ] [ /DIM=d /P ] waveA [ /D = destWaveA ] [ , waveB [ /D = destWaveB ] [ , ... ] ]
```

The **Reverse** operation reverses data in a wave in a specified dimension. **Reverse** does not accept text waves.

### Flags

/DIM = *d*                      Specifies the wave dimension to reverse.

*d=-1*: Treats entire wave as 1D (default).  
 For *d=0, 1, ...*, operates along rows, columns, etc.  
 /P Suppresses adjustment of dimension scaling. Without /P the scaled dimension value of reversed points remains the same.

#### Type Flags *(used only in functions)*

Reverse also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when it is needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-54 and **WAVE Reference Type Flags** on page IV-55 for a complete list of type flags and further details.

#### Wave Parameters

**Note:** *All* wave parameters must follow *wave* in the command. All wave parameter flags and type flags must appear immediately after the operation name (Reverse).

/D=*destWave* Specifies the name of the wave to hold the reversed data. It creates *destWave* if it does not already exist or overwrites it if it exists.

#### Details

If the optional /D = *destWave* flag is omitted, then the wave is reversed in place.

#### See Also

The **Sort** operation and **Sorting** on page III-132.

## rightx

### **rightx**(*waveName*)

The **rightx** function returns the X value corresponding to point N of the named 1D wave of length N.

#### Details

Note that the point numbers in a wave run from 0 to N-1 so there is no point with this X value. To get the X value of the last point in a wave (point N-1), use the following:

```
pnt2x(waveName, numpts(waveName)-1) // N = numpts(waveName)
```

which is more accurate than:

```
rightx(waveName) - deltax(waveName)
```

The **rightx** function is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details. The equivalent information for any dimension can be calculated this way:

$$IndexN = DimSize(wave, dim) * DimDelta(wave, dim) + DimOffset(wave, dim)$$

Here *IndexN* is the value of the scaled dimension index corresponding to element N of the dimension *dim* in a wave named *wave* that has N elements in that dimension.

#### See Also

The **deltax** and **leftx** functions, also the **pnt2x** and **numpts** functions.

For an explanation of waves and dimension scaling, see **Changing Dimension and Data Scaling** on page II-70.

For multidimensional waves, see **DimDelta**, **DimOffset**, and **DimSize**.

## root

### **root** [ : *dataFolderName* [ : *dataFolderName* [ : ... ] ] ] [ : *objectName* ]

Igor's data folder hierarchy starts with the root folder as its basis. The root data folder always exists and it contains all other objects (waves, variables, strings, and data folders). By default, the root data folder is the current data folder in a new experiment. In commands, **root** is used as part of a path specifying the location of a data object in the folder hierarchy.

#### See Also

Chapter II-8, **Data Folders**.

## Rotate

---

### Rotate

**Rotate** *rotPoints*, *waveName* [, *waveName*]...

The Rotate operation rotates the Y values of waves in wavelist by *rotPoints* points.

#### Parameters

If *rotPoints* is positive then values are rotated from the start of the wave toward the end and *rotPoints* values from the end of a wave wrap around to the start of the wave.

If *rotPoints* is negative then values are rotated from the end of the wave toward the start and *rotPoints* values from the start of a wave wrap around to the end of the wave.

#### Details

The X scaling of the named waves is changed so that the X values for the Y values remains the same except for the points that wrap around.

The Rotate operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details.

#### See Also

The shift parameter of the **WaveTransform** operation.

### round

**round** (*num*)

The round function returns the integer value closest to *num*.

The rounding method is “away from zero”.

#### See Also

The **ceil**, **floor**, and **trunc** functions.

### rtGlobals

**#pragma rtGlobals = 0, 1, or 2**

**#pragma rtglobals=1** is a compiler directive that creates global variables at runtime; not at compile time. This line must not be indented. **#pragma rtglobals=0** turns off runtime creation of globals.

If you create procedure files for use by others and you want to use the new logic operations such as `||` that require that **Silent 101** be in effect, then you should use

```
#pragma rtGlobals=2
```

in place of the normal `rtGlobals=1`.

#### See Also

The **Silent** operation and **#pragma**. See **The rtGlobals Pragma** on page IV-39.

## S

### s

The **s** function returns the current chunk index of the destination wave when used in a multidimensional wave assignment statement. The corresponding scaled chunk index is available as the **t** function.

#### Details

Unlike **p**, outside of a wave assignment statement, **s** does not act like a normal variable.

#### See Also

**Waveform Arithmetic and Assignments** on page II-80.

For other dimensions, the **p**, **r**, and **q** functions.

For scaled dimension indices, the **x**, **y**, **z** and **t** functions.

## Save

**Save** [*flags*] *waveList* [**as** *fileNameStr*]

The Save operation saves the named waves to disk.

### Parameters

*waveList* is either a list of wave names or, if the /B flag is present, a string list of references to waves. For example, the following commands are equivalent, assuming that the waves in question are in the root data folder and root is the current data folder:

```
Save/J wave0,wave1 as "Test.dat"
Save/J root:wave0,root:wave1 as "Test.dat"
Save/J/B "wave0;wave1;" as "Test.dat"
Save/J/B "root:wave0;root:wave1;" as "Test.dat"
String list="root:wave0;root:wave1;"; Save/J/B list as "Test.dat"
```

The form using the /B flag and a string containing a list of references to waves saves a very large number of waves using one command. This is not possible using a list of wave names because of the 400 character limit in a command. When using this form, the string must contain semicolon-separated wave names or data folder paths leading to waves. Liberal names in the string may be quoted or unquoted.

The file to be written is specified by *fileNameStr* and /P=*pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If it cannot determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

### Flags

/A[= <i>a</i> ]	Appends to the file rather than overwriting it (with /T, /G or /J). <i>a</i> =0: Does not append. <i>a</i> =1: Appends to the file with a blank line before the appended data (same as /A only). <i>a</i> =2: Appends to the file with no blank line before the appended data.
/B	The <i>waveList</i> parameter is a string containing a list of references to waves instead of a literal list of waves.
/C	Saves a copy of the wave when saving as Igor binary.
/DSYM= <i>dsStr</i>	Specifies a string containing the character to use as the decimal symbol for all numbers (default is a period). If <i>dsStr</i> is empty (""), then the decimal symbol is as defined in system preferences.
/E= <i>useEscapeCodes</i>	Determines whether to use escape sequences for special characters. /E=1: Converts carriage-return, linefeed, tab, and backslash characters to escape sequences when writing general or delimited text files (default; same as no /E). /E=0: No escape sequences used in general or delimited text files. When saving text waves containing backslashes (such as Windows paths) in a file intended for another program, you probably should use /E=0.
/F	Writes delimited and general text files with numeric formatting as it appears in the top table. Has no effect if there is no top table or if the wave being saved does not appear in the top table.
/G	Saves waves in general text format.
/I	presents a dialog from which you can specify file name and folder.
/J	Saves waves in tab-delimited text format.
/M= <i>termStr</i>	Specifies the terminator character or characters to use at the end of each line of text. The default is /M="\r", which uses a carriage return character. This is the Macintosh convention. To use the Windows convention, carriage return plus linefeed, specify /M="\r\n". To use the Unix convention, just a linefeed, specify /M="\n".
/O	Overwrites file if it exists already.
/P= <i>pathName</i>	Specifies the folder to store the file in. <i>pathName</i> is the name of an existing symbolic path.
/T	Saves waves in Igor Text format.

## Save

---

*/U*={*writeRowLabels*, *rowPositionAction*, *writeColLabels*, *colPositionAction*}

These parameters affect the saving of a matrix (2D wave) to a delimited text (/J) or general text (/G) file. They are accepted no matter what the save type is but are ignored when they don't apply.

If *writeRowLabels* is nonzero, Save writes the row labels of the matrix as the first column of data in the file.

*rowPositionAction* has one of the following values:

- 0: Don't write a row position column.
- 1: Writes a row position column based on the row scaling of the matrix wave.
- 2: Writes a row position column based on the contents of the row position wave for the matrix. The row position wave is an optional 1D wave whose name is the same as the matrix wave but with the suffix "\_RP".

*writeColumnLabels* and *columnPositionAction* have analogous meanings. The suffix used for the column position wave is "\_CP".

See Chapter II-9, **Importing and Exporting Data**, for further details.

*/W*

Saves wave names (with /G or /J).

### Details

The Save operation saves only the named waves; it does not save the entire experiment.

Waves saved in Igor binary format are saved one wave per file. If you are saving more than one wave, you must not specify a *fileNameStr*. Save will give each file a name which consists of the wave name concatenated with ".ibw".

In a general text file (/G), waves with different numbers of points are saved in different groups. Waves with different precisions and number types are saved in same group if they have the same number of points.

In a tab-delimited text file (/J), all waves are saved in one group whether or not they have the same number of points.

If you save multiple 2D waves, the blocks of data are written one after the other.

If you save 3D waves, the data for each wave is written as a contiguous block having as many columns as there are columns in the wave, and R\*L rows, where R is the number of rows in the multidimensional wave and L is the number of layers. All rows for layer 0 are saved followed by all rows for layer 1, and so on.

If you save 4D waves, the data for each wave is written as a contiguous block having R\*L\*C rows, where R is the number of rows, L is the number of layers and C is the number of chunks. Igor writes all data for chunk 0 followed by all data for chunk 1, and so on.

The Save operation will always present a save dialog if you try to save to an existing file without using the overwrite flag.

Here are some details about saving an Igor binary file.

If you omit the path or the file name, the Save operation will normally present a save dialog. However, if the wave has already been saved to a stand-alone file and if you use the overwrite flag, it will save the wave to the same file without a dialog. Also, if the wave has never been saved and the current experiment is an unpacked experiment, it will save to the home folder without a dialog.

If you use */P=pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-30 for details.

### Examples

This function uses the string list of references to waves to save some or all of the waves in the current data folder:

```
Function SaveWavesFromCurrentDF(matchStr)
    String matchStr // As for the WaveList function.
    String list
    list = WaveList(matchStr, ";", "")
    Save/O/J/W/I/B list
End
```

For example, to save all of the waves in the current data folder, execute:

```
SaveWavesFromCurrentDF("*")
```

To save those waves in the current data folder whose name starts with "wave", execute:

```
SaveWavesFromCurrentDF("wave*")
```

This function saves all of the waves used in a particular graph:

```
Function SaveWavesFromGraph(graphName)           // Saves all waves in graph.
  String graphName                               // "" for top graph.
  String list, traceList, traceName
  Variable index = 0
  list = ""
  traceList = TraceNameList(graphName, ";", 1)
  do
    traceName = StringFromList(index, traceList, ";")
    if (strlen(traceName) == 0)
      break
    endif
    Wave w = TraceNameToWaveRef(graphName, traceName)
    list += GetWavesDataFolder(w,2) + ";"
    index += 1
  while(1)
  if (strlen(list) > 0)
    Save/O/J/W/I/B list
  endif
End
```

**See Also**

Saving Waves on page II-157.

## SaveData

**SaveData** [*flags*] *fileOrFolderNameStr*

The SaveData operation writes data from the current data folder of the current experiment to a packed experiment file on disk or to a file system folder. "Data" means Igor waves, numeric and string variables, and data folders containing them. The data is written as a packed experiment file or as unpacked Igor binary files in a file-system folder.

**Warning:** If you make a mistake using SaveData, it is possible to overwrite critical data, even entire folders containing critical data. It is your responsibility to make sure that any file or folder that you can not afford to lose is backed up. If you provide procedures for use by other people, you should warn them as well.

SaveData provides a way to save data for archival storage or unload data from memory during a lengthy process like data acquisition. The file or files that SaveData writes are disassociated from the current experiment.

Use SaveData to save experiment data using Igor procedures. To save experiment data interactively, use the Save Copy button in the Data Browser (Data menu).

### Parameters

*fileOrFolderNameStr* specifies the packed experiment file (if /D is omitted) or the file system folder (if /D is present) in which the data is to be saved. The documentation below refers to this file or folder as the "target".

If you use a full or partial path for *fileOrFolderNameStr*, see **Path Separators** on page III-382 for details on forming the path.

If *fileOrFolderNameStr* is omitted or is empty (""), SaveData displays a dialog from which you can select the target. You also get a dialog if the target is not fully specified by *fileOrFolderNameStr* or the /P=*pathName* flag.

### Flags

/D [=d]	Writes to a file-system folder (a directory). If omitted, SaveData writes to an Igor packed experiment file.
d=1	If the target folder already exists, the new data is "mixed-in" with the data already there (same as /D).
d=2	If the target folder already exists, <b>it is completely deleted before the writing of data starts.</b>
	If in doubt, use /D=1. See <b>Details</b> below.
/I	Presents a dialog in which you can interactively choose the target.
/J= <i>objectNamesStr</i>	Saves only the objects named in the semicolon-separated list of object names. See <b>Details</b> below.

## SaveData

---

*/L=saveFlags* Controls what kind of data objects are saved with a bit for each data type:

<i>saveFlags</i>	Bit Number	Saves this Type of Object
1	0	Waves
2	1	Numeric variables
4	2	String variables

To save multiple data types, sum the values shown in the *saveFlags* column. For example, */L=1* saves waves only, */L=2* saves numeric variables only and */L=3* saves both waves and numeric variables.

If */L* is not specified, all of these object types are saved. This is equivalent to */L=7*. All other bits are reserved and must be set to zero. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

*/M=modDateTime* Saves waves modified on or after the specified modification date/time. Waves modified before *modDateTime* will not be saved. Applies to waves only (not variables or strings).

*modDateTime* is in standard Igor time format — seconds since 1/1/1904. If *modDateTime* is zero, all waves will be saved, as if there were no */M* flag at all.

*/O* Overwrites existing files or folders on disk.

**Warning:** If you use the */O* flag and if the target already exists, it will be overwritten without any warning. If you use */O* with */D=2*, **you will completely overwrite the target folder and all of its contents, including subfolders**. Do not use */O* with */D* unless you are absolutely sure you know what you are doing.

*/P=pathName* Specifies the folder in which to save the specified file or folder.

*pathName* is the name of an Igor symbolic path, created via `NewPath`. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-30 for details.

When used with the */D* flag, if */P=pathName* is present and *fileOrFolderNameStr* is ":", the target is the directory specified by */P=pathName*.

*/Q* Suppresses normal messages in the history area.

*/R* Recursively saves subdata folders.

*/T [=topLevelName]* Creates an enclosing data folder in the target with the specified name, *topLevelName*, and writes the data to the new data folder.

If just */T* is specified, it creates an enclosing data folder in the target using the name of the data folder being saved. However, if the data folder being saved is the root data folder, the name `Data` is used instead of `root`. In packed experiment files and unpacked experiment folders, the root data folder is implicit.

If */T* is omitted, the contents of the current data folder are saved with no enclosing data folder.

### Details

If */J=objectNamesStr* is used, then only the objects named in *objectNamesStr* are saved. For example, specifying */J="wave0;wave1;"* will save only the two named waves, ignoring any other data in all data folders.

The list of object names used with */J* must be semicolon-separated. A semicolon after the last object name in the list is optional. The object names must not be quoted even if they are liberal. The list is limited to 1000 characters.

Using */J=""* acts like no */J* at all.

The */M=modDateTime* flag can be used in data acquisition projects to save only those waves modified since the previous save. For example, assume that we have a global variable in the root data folder named `gLastWaveSaveDateTime`. Then this function will write out only those waves modified since the previous save:

```
Function SaveModifiedWaves(savePath)
    String savePath          // Symbolic path pointing to output directory
    NVAR lastSave = root:gLastWaveSaveDateTime
    SaveData/O/P=$savePath/D=1/L=1/M=(lastSave) ":"
    lastSave = datetime
End
```

Because the datetime function and the wave modification date have a coarse resolution (one second), this function may sometimes save the same wave twice.

The /M flag makes sense only in conjunction with the /D=1 flag because /D=1 is the only way to mix-in new data with existing data.

### Writing to a Packed Experiment File

When writing to a packed file, SaveData creates a standard packed Igor experiment file which you can open as an experiment, browse using the Data Browser, or access using the **LoadData** operation.

If you do not use the /O (overwrite) flag and the packed file already exists on disk, SaveData will present a dialog to confirm which file you want to write to. If you use the /O flag, SaveData will overwrite without presenting a dialog. When writing a packed file, SaveData always completely overwrites the preexisting packed file.

Appending to a packed experiment file is not supported because dealing with the possibility of name conflicts (e.g., two waves with the same name in the same data folder in the packed experiment file) would be technically difficult, very slow and errors would result in corrupted files.

### Writing to a File-System Folder

When saving to a folder on disk, SaveData writes wave files, variables files, and subfolders. This resembles the experiment folder of an unpacked experiment, but it does not contain other unpacked experiment files, such as history or procedures. You can browse the folder using the Data Browser or access it using the **LoadData** operation.

If the target directory does not exist, SaveData creates it.

If you do not use the /O (overwrite) flag and the target folder already exists on disk, SaveData will present a dialog to confirm that you want to write to it. SaveData checks for the existence of the top file system folder only. For example, if you write data to hd:Data:Run1, SaveData will display a dialog if hd:Data:Run1 exists. But SaveData will not display a dialog for any folders inside hd:Data:Run1.

If you use the /O flag, SaveData will write without presenting a dialog.

When writing to a directory, SaveData can operate in one of two modes. If you use /D=1 or just /D, SaveData operates in “mix-in” mode. If you use /D=2, SaveData operates in “delete” mode.

**Warning:** If the target directory exists and delete mode is used, SaveData deletes the target directory and all of its contents. Then SaveData creates the target directory and writes the data to it. This is a complete overwrite operation.

If the target directory exists and mix-in mode is used, SaveData does not do any explicit deletion. It writes data to the target directory and any subdirectories. Conflicting files in any directory are overwritten but other files are left intact.

To prevent you from inadvertently deleting an entire volume, SaveData will not permit you to target the root directory of any volume. You must target a subdirectory.

The /J flag will not work as expected when writing numeric and string variables in mix-in mode. Instead of mixing-in the specified variables, SaveData will overwrite all variables already in the target. This is because all numeric and string variables in a particular data folder are stored in a single file-system folder (named “variables”), so it is not possible to mix-in. Since waves are written one-to-a-file, /J will work as expected for waves.

When SaveData writes a wave to a file-system folder, the file name for the wave is the same as the wave name, with the extension “.ibw” added. This is true even if the wave in the experiment was loaded from a file with a different name. If appending the extension would make the file name too long, it is not appended. Igor limits file names to 31 characters on Macintosh and 255 characters on Windows.

### Outputs

SaveData sets the variable V\_flag to zero if the operation succeeded or to nonzero if it failed. The main use for this is to determine if the user clicked Cancel during an interactive save. This would occur if you use the /I flag or if you omit /O and the target already exists. V\_flag will also be nonzero if an error occurs during the save.

SaveData sets the string variable S\_path to the full file system path to the file or folder that was written. S\_path uses Macintosh path syntax (e.g., "hd:FolderA:FolderB:"), even on Windows. When saving unpacked, S\_path includes a trailing colon.

### Examples

Write the contents of the current data folder and all subdata folders to a packed experiment file:

## SaveExperiment

---

```
Function SaveDataInPackedFile(pathName, fileName)
  String pathName          // Name of symbolic path
  String fileName          // Name of packed file to be written
  SaveData/R/P=$pathName fileName
End
```

Write the contents of the current data folder and all subdata folders to an unpacked file-system folder:

```
Function SaveDataInUnpackedFolder(pathName, folderName)
  String pathName          // Name of symbolic path
  String folderName        // Name of file-system folder
  SaveData/D=1/R/P=$pathName folderName
End
```

Copy the contents of an unpacked file-system folder to a packed experiment file:

```
Function TransferUnpackedToPacked(path1, folderName, path2, fileName)
  String path1             // Points to parent of unpacked folder
  String folderName        // Name of folder containing unpacked data
  String path2             // Points to folder where file is to be written
  String fileName          // Name of packed file to be written
  String savedDF = GetDataFolder(1)
  NewDataFolder/O/S :TempTransfer
  // Load all data from the unpacked folder.
  LoadData/D/Q/R/P=$path1 folderName
  // Save all data to the packed file.
  SaveData/R/P=$path2 fileName
  KillDataFolder :          // Kill TempTransfer
  SetDataFolder savedDF
End
```

The **LoadData** and **SaveGraphCopy** operations; the **SpecialDirPath** function. **Saving Package Preferences** on page IV-180; Chapter II-9, **Importing and Exporting Data**; **Data Browser** on page II-114.

## SaveExperiment

**SaveExperiment** [/C/P=*pathName*] [as *fileName*]

The SaveExperiment operation saves the current experiment.

### Parameters

The optional *fileName* string contains the name of the experiment to be saved. *fileName* can be the currently open experiment, in which case it overwrites the experiment file.

If *fileName* and *pathName* are omitted and the experiment is Untitled, you will need to locate where the experiment file will be saved interactively via a dialog.

If you use a full or partial path for *pathName*, see **Path Separators** on page III-382 for details on forming the path.

### Flags

/C	Saves an experiment copy (valid only when <i>fileName</i> or <i>pathName</i> is provided or both if experiment is Untitled).
/P= <i>pathName</i>	Specifies folder in which to save the experiment. <i>pathName</i> is the name of an existing symbolic path.

### Details

SaveExperiment acts like the Save menu command in the File menu. If the experiment is associated with an already saved file, then SaveExperiment with no parameters will simply save the current experiment. If the experiment resides only in memory and has not yet been saved, then a dialog will be presented unless the path and file name are specified.

If you use a full path in the name you will not need the /P flag. If instead you use /P=*pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\Folder1\". See **Symbolic Paths** on page II-30 for details.

## SaveGraphCopy

**SaveGraphCopy** [*flags*][*as fileNameStr*]

The SaveGraphCopy operation saves a graph and its waves in an Igor packed experiment file.

### Parameters

The file to be written is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

### Flags

<i>/I</i>	Presents a dialog from which you can specify file name and folder.
<i>/O</i>	Overwrites file if it exists already.
<i>/P=pathName</i>	Specifies the folder to store the file in. <i>pathName</i> is the name of an existing symbolic path.
<i>/W=winName</i>	<i>winName</i> is the name of the graph to be saved. If <i>/W</i> is omitted or if <i>winName</i> is "", the top graph is saved.
<i>/Z</i>	Errors are not fatal and error dialogs are suppressed. See Details.

### Details

The main uses for saving as a packed experiment are to save an archival copy of data or to prepare to merge data from multiple experiments (see **Merging Experiments** on page II-27). The resulting experiment file preserves the data folder hierarchy of the waves displayed in the graph starting from the "top" data folder, which is the data folder that encloses all waves displayed in the graph. The top data folder becomes the root data folder of the resulting experiment file. Only the graph, its waves, dashed line settings, and any pictures used in the graph are saved in the packed experiment file, not procedures, variables, strings or any other objects in the experiment.

SaveGraphCopy does not work well with graphs containing controls. First, the controls may depend on waves, variables or FIFOs (for chart controls) that SaveGraphCopy will not save. Second, controls typically rely on procedures which are not saved by SaveGraphCopy.

SaveGraphCopy does not know about dependencies. If a graph contains a wave, wave0, that is dependent on another wave, wave1 which is not in the graph, SaveGraphCopy will save wave0 but not wave1. When the saved experiment is open, there will be a broken dependency.

SaveGraphCopy sets the variable *V\_flag* to 0 if the operation completes normally, to -1 if the user cancels, or to another nonzero value that indicates that an error occurred. If you want to detect the user canceling an interactive save, use the */Z* flag and check *V\_flag* after calling SaveGraphCopy.

The **SaveData** operation also has the ability to save a graph to a packed experiment file. SaveData is more complex but a bit more flexible than SaveGraphCopy.

### Examples

This function saves all graphs in the experiment to individual packed experiment files.

```
Function SaveAllGraphsToPackedFiles(pathName)
    String pathName          // Name of an Igor symbolic path.
    String graphName
    Variable index
    index = 0
    do
        graphName = WinName(index, 1)
        if (strlen(graphName) == 0)
            break
        endif
        String fileName
        sprintf fileName, "%s.pxp", graphName
        SaveGraphCopy/P=$pathName/W=$graphName as fileName
        index += 1
    while(1)
End
```

### See Also

SaveTableCopy and SaveData operations; Merging Experiments on page II-27.

## SaveNotebook

**SaveNotebook** [*flags*] *notebookName* [*as fileNameStr*]

The SaveNotebook operation saves the named notebook.

### Parameters

The file to be written is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

### Flags

*/H={encodingName, writeParagraphProperties, writeCharacterProperties, PNGOrJPEG, quality, bitDepth}*  
Controls the creation of an HTML file.

#### *encodingName*

Specifies the HTML file encoding. The recommended value for most purposes is "UTF-8". See **Details** for more information.

#### *writeParagraphProperties*

Determines what paragraph properties SaveNotebook will write to the HTML file. This is a bitwise parameter with the bits defined as follows:

Bit 0: Write paragraph alignment.

Bit 1: Write first indent.

Bit 2: Write minimum line spacing.

Bit 3: Write space-before and space-after paragraph.

All other bits are reserved for future use and should be set to zero.

#### *writeCharacterProperties*

Determines what character properties SaveNotebook will write to the HTML file. This is a bitwise parameter with the bits defined as follows:

Bit 0: Write font families.

Bit 1: Write font sizes.

Bit 2: Write font styles.

Bit 3: Write text colors.

Bit 4: Write text vertical offsets.

All other bits are reserved for future use and should be set to zero.

If you set bit 2, SaveNotebook exports only the bold, underline, and italic styles because other character styles are not supported by HTML.

#### *PNGOrJPEG*

Determines whether SaveNotebook will write picture files as PNG or JPEG:

0: PNG (default).

1: JPEG.

2: JPEG.

Prior to Igor Pro 5, *PNGOrJPEG=2* wrote as JPEG if QuickTime JPEG support was available or as PNG otherwise. As of Igor Pro 5, which has built-in JPEG support, both *PNGOrJPEG=2* and *PNGOrJPEG=1* write as JPEG. For both codes, QuickTime is used if it is available because it supports the quality and depth parameters although built-in JPEG support currently always uses *quality=0.9*. See **Details** for more on HTML picture files.

The next two parameters, *quality*, and *bitDepth*, are used only when writing JPEG files using QuickTime.

<i>quality</i>	Specifies the degree of compression or image quality when writing pictures as JPEG files. It is a value from 1.0 (default) to 0.0, with 1.0 giving the greatest quality but largest file size and 0.0 giving the least quality but smallest file size. Use the highest quality that gives an acceptable file size. Often this will be 1.0.
<i>bitDepth</i>	Specifies the color depth when writing pictures as JPEG files. It specifies the desired bit depth of the picture. Only the following values are legal: 1, 8 (default), 16, 24, 32. For most Web use, 8 is fine. As of QuickTime 4, QuickTime ignores this parameter.
/I	Saves interactively. A dialog is displayed.
/M= <i>messageStr</i>	Specifies prompt message used in save dialog.
/O	Overwrites existing file without asking permission.
/P= <i>pathName</i>	Specifies the folder to store the file in. <i>pathName</i> is the name of an existing symbolic path.
/S= <i>saveType</i>	<ol style="list-style-type: none"> <li>1: Normal save (default).</li> <li>2: Save-as.</li> <li>3: Save-a-copy.</li> <li>4: Export as RTF (Rich Text Format).</li> <li>5: Export as HTML (Hypertext Markup Language).</li> <li>6: Export as plain text.</li> <li>7: Export as formatted notebook.</li> </ol>

### Details

Interactive (/I) means that Igor displays the Save, Save As, or Save a Copy dialog.

The save will be interactive under the following conditions:

- You include the /I flag and the *saveType* is 2, 3, 4, 5, 6, or 7.
- *saveType* is 2, 3, 4, 5, 6, or 7 and you do not specify the path or filename.

If the *saveType* is normal and the notebook has previously been saved to a file then the /I flag, the path and file name that you specify, if any, are ignored and the notebook is saved to its associated file without user intervention.

The full path to the saved file is stored in the string S\_path. If the save was unsuccessful, S\_path will be "".

If you use /P=*pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-30 for details.

For background information on writing RTF files, see **Import and Export Via Rich Text Format Files** on page III-21.

For background information on writing HTML files, see **Exporting a Notebook as HTML** on page III-23.

For background information regarding the HTML *encodingName* parameter, see **HTML Character Encoding** on page III-26. This table lists how Igor responds to various values for this parameter:

"UTF-8"	Encodes the document using the UTF-8 encoding which is a kind of packed Unicode. It is good for documents that contain non-Roman text, such as symbols and Asian text. This is the best choice for most documents.
"UTF-2"	Encodes the document using the UTF-2 encoding which is 16-bit Unicode. It is generally not recommended because some browsers don't support it. However, as time goes by, browser support will improve.
"Native"	Writes the document using the native character set of the operating system. On Macintosh, this equates to "mac" (the Mac OS Roman character set). On Windows, it equates to "Windows-1252" (the Windows Western character set). This may give better results than UTF-8 for some documents and with some browsers but you should use it only if you determine that UTF-8 doesn't work for your application.
""	Writes the document using the native character set of the operating system but omits the Content-Type meta tag.

In addition, you can provide any other string of 63 or fewer bytes. The main use for this is for documents that are primarily in an Asian language. For example, if your document is primarily in Japanese, then the characters in the document are already in the Shift-JIS encoding. You can specify "Shift-JIS" as the

## SavePackagePreferences

---

*encodingName*. This uses "Shift-JIS" in the Content-Type meta tag and to write the text out without any special encoding. The main advantage of this technique over the UTF-8 encoding is that a file written using Shift-JIS can be edited in Igor or other commonly-available text editors while UTF-8 can not.

When creating an HTML file, SaveNotebook can write pictures using the PNG or JPEG graphics formats. PNG support is built into Igor Pro. Built-in JPEG support was added in Igor Pro 5. Previously Igor used QuickTime to write JPEG files. It still does if QuickTime is available but if not, it uses built-in routines. For most applications, the only reason to use JPEG rather than PNG is that some old web browsers do not support PNG.

Chapter III-1, **Notebooks**.

**Setting Bit Parameters** on page IV-11 for further details about bit settings.

## SavePackagePreferences

**SavePackagePreferences** [/FLSH=*flush* /P=*pathName*] *packageName*, *prefsFileName*, *recordID*, *prefsStruct*

The SavePackagePreferences operation saves preference data in the specified structure so that it can be accessed later via by the **LoadPackagePreferences** operation.

The data is stored in memory and by default flushed to disk when the current experiment is saved or closed and when Igor quits.

If the /P flag is present then the location on disk of the preference file is determined by *pathName* and *prefsFileName*. However in the usual case the /P flag will be omitted and the preference file is located in a file named *prefsFileName* in a directory named *packageName* in the Packages directory in Igor's preferences directory.

**Note:** You must choose a very distinctive name for *packageName* as this is the only thing preventing collisions between your package and someone else's package.

See **Saving Package Preferences** on page IV-180 for background information and examples.

### Parameters

*packageName* is the name of your package of Igor procedures. It is limited to 31 characters and must be a legal name for a directory on disk. This name must be very distinctive as this is the only thing preventing collisions between your package and someone else's package.

*prefsFileName* is the name of a preference file to be saved by SavePackagePreferences. It should include an extension, typically ".bin".

*prefsStruct* is the structure containing the data to be saved in the preference file on disk.

*recordID* is a unique positive integer that you assign to each record that you store in the preferences file. If you store more than one structure in the file, you would use distinct *recordIDs* to identify which structure you want to save. In the simple case you will store just one structure in the preference file and you can use 0 (or any positive integer of your choice) as the *recordID*.

### Flags

/FLSH=*flush* Controls when the data is actually written to the preference file:  
0: The data will be flushed to disk when the current experiment is saved, reverted or closed or when Igor quits. This is the default behavior used when /FLSH is omitted and is recommended for most purposes.  
1: The data is flushed to disk immediately.

/P=*pathName* Specifies the directory in which to save the file specified by *prefsFileName*.  
*pathName* is the name of an existing symbolic path. See **Symbolic Paths** on page II-30 for details.  
/P=\$<empty string variable> acts as if the /P flag were omitted.

### Details

SavePackagePreferences set the variable V\_flag to 0 if preferences were successfully saved or to a nonzero error code if they were not saved. The latter case is unlikely and would indicate some kind of corruption such as if Igor's preferences directory were deleted.

### Example

See the example under **Saving Package Preferences in a Special-Format Binary File** on page IV-181.

See Also  
LoadPackagePreferences.

## SavePICT

**SavePICT** [*flags*] [*as fileNameStr*]

The SavePICT operation creates a picture file representing the top graph, table or layout. The picture file can be opened by many word processing, drawing, and page layout programs.

To use any of the QuickTime graphic export formats (/T flag), you will need to have QuickTime 4 or later installed (full install) in your system.

### Parameters

The file to be written is specified by *fileNameStr* and /P=*pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

If you omit *fileNameStr* but include /P=*pathName*, SavePICT writes the file using a default file name. The default file name is the window name followed by an extension, such as ".png", ".emf" or ".PICT", that depends on the graphic format being exported.

If you specify the file name as "Clipboard", and do *not* specify a /P=*pathName*, Igor copies the picture to the Clipboard, rather than to a file. QuickTime formats (/T) can not be put on the Clipboard.

If you specify the file name as "\_string\_" the output will be saved into a string variable named S\_Value, which is used with the **ListBox** binary bitmap display mode.

### Flags

/B= <i>dpi</i>	Controls image resolution in dots-per-inch ( <i>dpi</i> ). The legal values for <i>dpi</i> are $n*72$ where <i>n</i> can be from 1 to 8. The actual image <i>dpi</i> is not used. Igor calculates <i>n</i> from your value of <i>dpi</i> and then multiplies <i>n</i> by your computer's screen resolution. This is because bitmap images that are not an integer multiple of the screen resolution look quite bad. The /B flag can be used with QuickTime export types (/T). Also see the /RES flag.
/C= <i>c</i>	Specifies color mode. <i>c</i> =0: Black and white. <i>c</i> =1: RGB color (default). <i>c</i> =2: CMYK color (EPS and native TIFF only).
/D= <i>d</i>	Specifies bit depth for QuickTime image export. <i>d</i> may be 1, 8, 16, 24 (default), or 32 bits. Not all formats use depth. An intermediate picture at the current screen depth is used and may limit the quality.
/E= <i>e</i>	Sets graphics format used when exporting a graphic. See <b>Details</b> for formats. See also Chapter III-5, <b>Exporting Graphics (Macintosh)</b> , or Chapter III-6, <b>Exporting Graphics (Windows)</b> , for a description of these modes and when to use them.
/EF= <i>e</i>	Sets font embedding. <i>e</i> =0: No font embedding. <i>e</i> =1: Embed nonstandard fonts. <i>e</i> =2: Embed all fonts.
/I	Specifies that /W coordinates are inches.
/M	Specifies that /W coordinates are centimeters.
/N= <i>winSpec</i>	Deprecated: Igor Pro 4.09-compatibility version of /WIN.
/O	Overwrites file if it exists.
/P= <i>pathName</i>	Saves file into a folder specified by <i>pathName</i> , which is the name of an existing symbolic path.

<code>/PICT=<i>pict</i></code>	Saves specified named picture rather than the target window. Native format of the picture is used and all format flags are ignored.
<code>/PLL=<i>p</i></code>	Specifies Postscript language level when used in conjunction with EPS export. <i>p</i> =1: For very old Postscript printers. <i>p</i> =2: For all other uses (default).
<code>/Q=<i>q</i></code>	Sets quality factor (0.0 is lowest, 1.0 is highest). Default is dependent on individual format. Used only by lossy formats such as QuickTime JPEG.
<code>/R=<i>resID</i></code>	Saves the picture in a resource fork with resource ID= <i>resID</i> , where <i>resID</i> is between 1 and 32767.  This flag is meaningful on Macintosh only. It is ignored on Windows. Also, it does not work with EPS or PNG graphics.
<code>/RES=<i>dpi</i></code>	Controls the resolution of image formats in dots-per-inch. Unlike the similar <code>/B</code> flag, the value for <code>/RES</code> is the actual output resolution and is useful when your publisher demands a specific resolution. The <code>/RES</code> flag can be used with QuickTime export types ( <code>/T</code> ).
<code>/S</code>	Suppresses the preview that is normally included with an EPS file.
<code>/SNAP=<i>s</i></code>	Saves snapshot of a graph window. <i>s</i> =1: Include all controls in capture. <i>s</i> =2: Capture only window data content.  Snapshot mode is available only for graphs and only for bitmap exports as PNG, JPEG, or TIFF at screen resolution. When using <code>/W</code> to specify the size, the capture is sized to fit within the specified rectangle while maintaining the window aspect ratio. Size is in pixels.
<code>/T=<i>t</i></code>	Specifies a QuickTime export type. An error will be generated if QuickTime is not present or if the desired export type is not available. <i>t</i> is a string containing a 4 character code for the export type. Valid types include "PNGf" for PNG, "TIFF" for TIFF, "JPEG" for JPEG. GIF is "GIFf" but is not currently supported by QuickTime presumably due to the patent situation. This might change in the future if Apple or a third party provides a component for GIF writing.
<code>/TRAN[=<i>1 or 0</i>]</code>	Makes white background areas transparent using an RGBA type PNG when used with native PNG export of graphs or page layouts. In layouts, only embedded graphs and textboxes marked as transparent will be transparent. Nonembedded graphs, pictures, and tables will be opaque. PNG transparency is not honored when placed in Igor.
<code>/W=(<i>left,top,right,bottom</i>)</code>	Specifies the size of the picture when exporting a graph. If <code>/W</code> is omitted, it uses the graph window size.  When exporting a page layout, specifies the part of the page to export. Only objects that fall completely within the specified area are exported. If <code>/W</code> is omitted, the area of the layout containing objects is exported.  Coordinates for <code>/W</code> are in points unless <code>/I</code> or <code>/M</code> are specified before <code>/W</code> .
<code>/WIN=<i>winSpec</i></code>	Saves the named window or subwindow. <i>winSpec</i> can be just a window name, or a window name following by a "#" character and the name of the subwindow, as in <code>/WIN=Panel10#G0</code> .
<code>/Z</code>	Errors are not fatal. <code>V_flag</code> is set to zero if no error, else nonzero if error.

### Details

SavePICT sets the variable `V_flag` to 0 if the operation succeeds or to a nonzero error code if it fails.

If you specify a path using the `/P=pathName` flag, then Igor saves the file in the folder identified by the path. Note that *pathName* is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "`hd:Folder1:`" or "`C:\\Folder1\\`". See **Symbolic Paths** on page II-30 for details. Otherwise, with no path specified, Igor presents a standard save dialog to let you specify where the file is to be saved.

When writing an EPS file, it normally includes a screen preview. On Macintosh, this is a PICT in the resource fork of the file. On Windows, it is a TIFF embedded in the EPS file. Using the `/S` flag, you can suppress the preview to save disk space, to work around a program that is confused by the preview, or to create a completely platform-neutral file.

On Macintosh, the picture is normally written to the data fork of the file. Most applications read it from the data fork. Some, however, read PICTs from the resource fork. If you use */R=resID*, it writes the PICT to the resource fork of the file, using *resID* as the resource ID.

Graphics formats, specified via */E*, are as follows:

<i>/E</i> Value	Macintosh File Format	Windows File Format
-8	PDF file.	PDF file.
-7	TIFF file. Lossless but larger file than PNG; best for text, graph traces, and simple images with sharp edges. The default resolution is 72 dpi. You can specify the resolution with the <i>/B</i> or <i>/RES</i> flag. Cross-platform compatible.	
-6	JPEG file. Lossy compression; best used for grayscale and color images with smooth tones. The <i>/Q</i> flag specifies compression quality and the <i>/B</i> or <i>/RES</i> flag sets the resolution. Cross-platform compatible.	
-5	PNG (Portable Network Graphics) file. Lossless compression; best for text, graph traces, and simple images with sharp edges. The default resolution is 72 dpi. Specify the resolution with <i>/B</i> or <i>/RES</i> . Cross-platform compatible.	
-4	High resolution bitmap PICT file. Default resolution is 288 dpi. Specify the resolution with <i>/B</i> or <i>/RES</i> .	Device-independent bitmap file (DIB). Default resolution is 4x screen resolution. Specify the resolution with <i>/B</i> or <i>/RES</i> .
-3	Encapsulated PostScript (EPS) file.	Encapsulated PostScript (EPS) file.
-2	High-resolution PICT.	High-resolution enhanced metafile.
-1	Obsolete – Pure PostScript PICT.	Obsolete – PostScript-enhanced metafile.
0	Obsolete – PostScript PICT with QuickDraw text.	Obsolete – PostScript-enhanced metafile.
1	Normal PICT.	Windows metafile at screen resolution (or any multiple of <i>/E</i> ≥ 1 resolution).
2	PICT at 2x size.	Windows metafile at 2x size.
4	PICT at 4x size.	Windows metafile at 4x size.
8	PICT at 8x size.	Windows metafile at 8x size.

**Note:** The Windows metafile format works on graph and table windows but does not work on page layout windows. The PostScript-enhanced metafile format works on graph windows only. If you attempt to use an unsupported format on a table or page layout window, SavePICT will use the enhanced metafile format instead.

#### See Also

The **ImageSave** operation for saving waves as PICTs and other image file formats. The **LoadPICT** operation.

See Chapter III-5, **Exporting Graphics (Macintosh)**, or Chapter III-6, **Exporting Graphics (Windows)**, for a description of the */E* modes.

## SaveTableCopy

**SaveTableCopy** [*flags*][*as fileNameStr*]

The SaveTableCopy operation saves a copy of the data displayed in a table on disk. The saved file can be an Igor packed experiment file, a tab-delimited text file, or a comma-separated values text file.

When saving as text, the data format matches the format shown in the table. Keep in mind that this will cause truncation if the underlying data has more precision than shown in the table. The point column is never saved.

#### Parameters

The file to be written is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor

## SaveTableCopy

---

can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

### Flags

<i>/A=a</i>	Appends data to the file rather than overwriting. <i>a=0</i> : Does not append. <i>a=1</i> : Appends to the file with a blank line before the appended data. <i>a=2</i> : Appends to the file with no blank line before the appended data. <i>/A</i> applies when saving text files and is ignored when saving packed experiment files. If the file does not exist, a new file is created and <i>/A</i> has no effect.
<i>/I</i>	Presents a dialog from which you can specify file name and folder.
<i>/M=termStr</i>	Specifies the terminator character or characters to use at the end of each line of text. The default is <i>/M="\r"</i> on Macintosh and <i>/M="\r\n"</i> on Windows; it is used when <i>/M</i> is omitted. To use the Unix convention, just a linefeed, specify <i>/M="\n"</i> .
<i>/N=n</i>	Specifies whether to use column names, titles, or dimension labels. <i>n</i> is a bitwise parameter with the bits defined as follows: Bit 0: Include column names or titles. The column title is included if it is not empty. If it is empty, the column name is included. Bit 1: Include horizontal dimension labels if they are showing in the table. The default setting for <i>n</i> is 1. All other bits are reserved and must be zero.
<i>/O</i>	Overwrites file if it exists already.
<i>/P=pathName</i>	Specifies the folder to store the file in. <i>pathName</i> is the name of an existing symbolic path.
<i>/S=s</i>	Saves all of the data in the table ( <i>s=0</i> ; default) or the selection only ( <i>s=1</i> ). <i>/S</i> applies when saving text files and is ignored when saving packed experiment files.
<i>/T=saveType</i>	Specifies the file format of the saved table. <i>saveType=0</i> : Packed experiment file. <i>saveType=1</i> : Tab-delimited text file. <i>saveType=2</i> : Comma-separated values text file. <i>saveType=3</i> : Space-delimited values text file.
<i>/W=winName</i>	<i>winName</i> is the name of the table to be saved. If <i>/W</i> is omitted or if <i>winName</i> is "", the top table is saved.
<i>/Z</i>	Errors are not fatal and error dialogs are suppressed. See Details.

### Details

The main uses for saving a table as a packed experiment are to save an archival copy of data or to prepare to merge data from multiple experiments (see **Merging Experiments** on page II-27). The resulting experiment file preserves the data folder hierarchy of the waves displayed in the table starting from the "top" data folder, which is the data folder that encloses all waves displayed in the table. The top data folder becomes the root data folder of the resulting experiment file. Only the table and its waves are saved in the packed experiment file, not variables or strings or any other objects in the experiment.

SaveTableCopy does not know about dependencies. If a table contains a wave, *wave0*, that is dependent on another wave, *wave1* which is not in the table, SaveTableCopy will save *wave0* but not *wave1*. When the saved experiment is open, there will be a broken dependency.

The main use for saving as a tab or comma-delimited text file is for exporting data to another program.

When calling SaveTableCopy from a procedure, you should call DoUpdate before calling SaveTable copy. This insures that the table is up-to-date if your procedure has redimensioned or otherwise changed the number of points in the waves in the table.

SaveTableCopy sets the variable *V\_flag* to 0 if the operation completes normally, to -1 if the user cancels, or to another nonzero value that indicates that an error occurred. If you want to detect the user canceling an interactive save, use the */Z* flag and check *V\_flag* after calling SaveTableCopy.

The **SaveData** operation also has the ability to save a table to a packed experiment file. SaveData is more complex but a bit more flexible than SaveTableCopy.

### Examples

This function saves all tables to a single tab-delimited text file.

```
Function SaveAllTablesToTextFile(pathName, fileName)
  String pathName          // Name of an Igor symbolic path.
  String fileName

  String tableName
  Variable index
  index = 0
  do
    tableName = WinName(index, 2)
    if (strlen(tableName) == 0)
      break
    endif
    SaveTableCopy/P=$pathName/W=$tableName/T=1/A=1 as fileName
    index += 1
  while(1)
End
```

### See Also

**SaveGraphCopy** and **SaveData** operations; **Merging Experiments** on page II-27.

## sawtooth

### **sawtooth**(*num*)

The sawtooth function returns  $((num + n2\pi) \bmod 2\pi) / 2\pi$  where *n* is used to correct if *num* is negative. Sawtooth is used to create arbitrary periodic waveforms like sine and cosine.

### Examples

```
wave1 = sawtooth(x)
```

creates a sawtooth in wave1 whose Y values range from 0 to 1 as its X values go through  $2\pi$  units.

```
wave1 = exp(sawtooth(x))
```

creates a series of exponentials in wave1 of amplitude exp(1) and period  $2\pi$ .

You can also use sawtooth to create periodic repetitions of a given part of a wave:

```
wave1 = wave2(sawtooth(x))
```

creates a periodic repetition of wave2 in wave1 given the correct X scaling for the waves.

## ScreenResolution

### **ScreenResolution**

The ScreenResolution function returns the logical resolution of your video display screen in dots per inch (dpi). On Macintosh this is always 72. On Windows it is usually 96 (small fonts) or 120 (large fonts).

## Secs2Date

### **Secs2Date**(*seconds*, *format*)

The Secs2Date function returns a string containing a date.

With *format* values 0, 1, and 2, the formatting of dates depends on your operating system and on your preferences entered in the Date & Time control panel (*Macintosh*) or the Regional Settings control panel (*Windows*).

If *format* is -1, the format is independent of the operating system. The fixed-length format is "*day / month / year (dayOfWeekNum)*", where *dayOfWeekNum* is 1 for Sunday, 2 for Monday... and 7 for Saturday.

### Parameters

*seconds* is the number of seconds from 1/1/1904 to the date to be returned.

*format* is a number between -1 and 2 which specifies how the date is to be constructed.

### Examples

```
Print Secs2Date(DateTime,-1)      // prints 15/03/1993 (2)
Print Secs2Date(DateTime,0)      // prints 3/15/93
```

## Secs2Time

---

```
Print Secs2Date(DateTime,1) // prints Monday, March 15, 1993
Print Secs2Date(DateTime,2) // prints Mon, Mar 15, 1993
```

### See Also

The `date`, `date2secs` and `DateTime` functions.

## Secs2Time

**Secs2Time(*seconds*, *format*, [*fracDigits*])**

The `Secs2Time` function returns a string containing a time.

### Parameters

*seconds* is the number of seconds from 1/1/1904 to the time to be returned.

*format* is a number between 0 and 5 that specifies how the time is to be constructed. It is interpreted as follows:

- 0: Normal time, no seconds.
- 1: Normal time, with seconds.
- 2: Military time, no seconds.
- 3: Military time, with seconds and optional fractional seconds.
- 4: Elapsed time, no seconds.
- 5: Elapsed time, with seconds and optional fractional seconds.

“Normal” formats (0 and 1) follow the preferred formatting of the short time format as set in the International control panel (*Macintosh*) or in the Regional and Language Options control panel (*Windows*).

“Military” means that the hour is a number from 0 to 23. Hours greater than 23 are wrapped.

“Elapsed” means that the hour is a number from -9999 to 9999. The result for hours outside that range is undefined.

The *fracDigits* parameter is optional and specifies the number of digits of fractional seconds. The default value is 0. The *fracDigits* parameter is ignored for *format*=0, 1, 2, and 4.

### Examples

```
Print Secs2Time(DateTime,0) // prints 1:07 PM
Print Secs2Time(DateTime,1) // prints 1:07:28 PM
Print Secs2Time(DateTime,2) // prints 13:07
Print Secs2Time(DateTime,3) // prints 13:07:29
Print Secs2Time(30*60*60+45*60+55,4) // Prints 30:45
Print Secs2Time(30*60*60+45*60+55,5) // Prints 30:45:55
```

### See Also

The `date`, `date2secs` and `DateTime` functions. Also, **Operators** on page IV-5 for `?:` details.

## SelectNumber

**SelectNumber(*whichOne*, *val1*, *val2* [, *val3*])**

The `SelectNumber` function returns one of *val1*, *val2*, or (optionally) *val3* based on the value of *whichOne*.

`SelectNumber(whichOne, val1, val2)` returns *val1* if *whichOne* is zero, else it returns *val2*.

`SelectNumber(whichOne, val1, val2, val3)` returns *val1* if *whichOne* is negative, *val2* if *whichOne* is zero, or *val3* if *whichOne* is positive.

### Details

`SelectNumber` works with complex (or real) *val1*, *val2*, and *val3* when the result is assigned to a complex wave or variable. (`Print` expects a real result, see the “causes error” example, below).

If *whichOne* is NaN, then NaN is returned.

*whichOne* must always be a real value.

Unlike the `?:` conditional operator, `SelectNumber` always evaluates all of the numeric expression parameters *val1*, *val2*, ...

`SelectNumber` works in a macro, whereas the conditional operator does not.

**Examples**

```

Print SelectNumber(0,1,2)           // prints 1
Print SelectNumber(0,1,2,3)        // prints 2
wv=SelectNumber(numtype(wv[p])==2,wv[p],0) // replace NaNs with zeros
// chooses among complex values
Variable/C cx= SelectNumber(negZeroPos,cmplx(-1,-1),0,cmplx(1,1))
// causes error because Print expects a real value (not complex)
Print SelectNumber(negZeroPos,cmplx(-1,-1),0,cmplx(1,1))
// The real function expects a complex result
Print real(SelectNumber(negZeroPos,cmplx(-1,-1),0,cmplx(1,1)))

```

**See Also**

The **SelectString** and **limit** functions, and **Waveform Arithmetic and Assignments** on page II-80. Also, **Operators** on page IV-5 for details about the ?: operator.

**SelectString**

**SelectString(*whichOne*, *str1*, *str2* [, *str3*])**

The SelectString function returns one of *str1*, *str2*, or (optionally) *str3* based on the value of *whichOne*.

SelectString(*whichOne*, *str1*, *str2*) returns *str1* if *whichOne* is zero, else it returns *str2*.

SelectString(*whichOne*, *str1*, *str2*, *str3*) returns *str1* if *whichOne* is negative, *str2* if *whichOne* is zero, or *str3* if *whichOne* is positive.

**Details**

If *whichOne* is NaN, then "" is returned.

*whichOne* must always be a real value.

Unlike the ?: conditional operator, SelectString always evaluates all of the string expression parameters *str1*, *str2*, ...

SelectString works in a macro, whereas the conditional operator does not.

**Examples**

```

Print SelectString(0,"hello","there") // prints "hello"
Print SelectString(1,"hello","there") // prints "there"
Print SelectString(-3,"hello","there","jack") // prints "hello"
Print SelectString(0,"hello","there","jack") // prints "there"
Print SelectString(100,"hello","there","jack") // prints "jack"

```

**See Also**

The **SelectNumber** function and **String Expressions** on page IV-12. Also, **Operators** on page IV-5 for details about the ?: operator.

**SetActiveSubwindow**

**SetActiveSubwindow *subWinName***

The SetActiveSubwindow operation specifies the subwindow that is to be activated. This command is mainly for use by recreation macros.

**Parameters**

*subWinName* is the name of an existing subwindow. Use `_endfloat_` for *subWinName* to make a newly-created floating panel not be the default target.

When identifying a subwindow with *subWinName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**SetAxis**

**SetAxis [*flags*] *axisName* [, *num1*, *num2*]**

The SetAxis operation sets the extent (or “range”) of the named axis.

**Parameters**

*axisName* is usually “left”, “right”, “top” or “bottom”, but it can also be the name of a free axis, such as “vertCrossing”.

## SetBackground

---

If *axisName* is a vertical axis such as “left” or “right” then *num1* sets the bottom end of the axis and *num2* sets the top end of the axis.

If *axisName* is a horizontal axis such as “top” or “bottom” then *num1* sets the left end of the axis and *num2* sets the right end of the axis.

You can flip the graph by reversing *num1* and *num2* (or by using /A/R). This is particularly useful for images, because Igor plots an image inverted.

### Flags

/A[= <i>a</i> ]	Autoscale axis (when used, <i>num1</i> , <i>num2</i> should be omitted) <i>a</i> =0: No autoscale. Same as no /A flag. <i>a</i> =1: Normal autoscale. Same as /A. <i>a</i> =2: Autoscale Y axis to a subset of the data defined by the current X axis range.
/E= <i>z</i>	Sets the treatment of zero when the axis is in autoscale mode. <i>z</i> =0: Normal mode where zero is not treated special. <i>z</i> =1: Forces the smaller end of the axis to be set to zero (autoscale from zero). <i>z</i> =2: Axis is symmetric about zero.
/N= <i>n</i>	Sets the algorithm for axis autoscaling. <i>n</i> =0: Normal mode; sets the axis limits equal to the data limits. <i>n</i> =1: Picks nice values for the axis limits. <i>n</i> =2: Picks nice values; also ensures that the data is inset from the axis ends.
/R	Reverses the autoscaled axis (smaller values at the left for horizontal axes, at the top for vertical axes) when used with /A. Although it only has an effect for autoscale, it can be used with nonautoscale version of SetAxis so that the next time the Axis Range tab is used the “reverse axis” checkbox will already be set.
/W= <i>winName</i>	Sets axes in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy.
/Z	No error reporting if named axis doesn’t exist in a style macro.

## SetBackground

### SetBackground *numericExpression*

The SetBackground operation sets *numericExpression* as the background task.

The background task runs while Igor is not busy with other things. Normally, there won’t be a background task. The most common use for the background task is to monitor or drive a continuous data acquisition process.

### Parameters

*numericExpression* is a single precision numeric expression that Igor executes when it isn’t doing anything else.

### Details

*numericExpression* is expected to return one of three numeric values:

- 0: Background task executed normally.
- 1: Background task wants to stop.
- 2: Background task encountered error and wants to stop.

Usually the expression will be a call to a user-defined numeric function or external function to drive or monitor data acquisition. The expression should be designed to execute very quickly and it should not present a dialog to the user nor should it create or destroy windows. Generally, it should do nothing more than store data into waves or variables. You can use Igor’s dependency mechanism to perform more extensive tasks.

SetBackground designates the background task but you must use CtrlBackground to start it. You can also use KillBackground to stop it. You can not call SetBackground from the background function itself.

**See Also**

The **BackgroundInfo**, **CtrlBackground**, **CtrlNamedBackground**, **KillBackground**, and **SetProcessSleep** operations, and **Background Task** on page IV-211.

**SetDashPattern**

**SetDashPattern** *dashNumber*, {*d1*, *s1* [, *d2*, *s2*]...}

The SetDashPattern operation defines a dashed-line pattern for a user-defined dashed line. These dashed lines are used by the drawing tools and the Modify Waves Appearance dialog, and are elsewhere referred to as “line styles”.

**Parameters**

*dashNumber* specifies which dash pattern is to be set. It must be between 1 and 17. Dash pattern 0 is reserved for a solid line.

0	_____	9	-----
1	.....	10	-----
2	.....	11	-----
3	-----	12	_____
4	.....	13	-----
5	-----	14	-----
6	-----	15	_____
7	-----	16	_____
8	-----	17	-----

{*d1,s1* [,*d2,s2*]...} defines the dash pattern. The dash pattern consists of 1 to 8 “dash,skip” pairs. Each pair consists of the number of drawn points followed by the number of skipped points.

*d1* specifies the number of drawn points and *s1* specifies the number of skipped points in the first “dash,skip” pair. *d2* and *s2* specify the number of drawn and skipped points in the second pair and so on. Each draw or skip value must be between 1 and 127.

**Details**

SetDashPattern updates *all* graphs, panels and layouts so that any dashed lines will be updated with the new pattern. If you repeatedly call SetDashPattern from within a macro, you should precede the commands with the PauseUpdate operation to prevent multiple updates (which would be slow).

Dashed lines may also be redefined by the Dashed Lines dialog which you can choose from the Misc menu.

The dashed line patterns are saved as part of the experiment. When a new experiment is opened, the preferred dash patterns are restored.

Some programs and printer drivers do not properly render dashed lines with many “dash,skip” pairs.

**Examples**

```
Make test; Display test
SetDashPattern 17, {20,3,15,8}           // sets last dashed line pattern
ModifyGraph lstyle(test)=17              // apply pattern to trace
```

**See Also**

**PauseUpdate** and **ResumeUpdate** operations, and **Dashed Lines** on page III-394.

**SetDataFolder**

**SetDataFolder** *dataFolderSpec*

The SetDataFolder operation sets the current data folder to the specified data folder.

**Parameters**

*dataFolderSpec* can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

**Examples**

```
SetDataFolder foo                       // Sets CDF to foo in the current data folder.
SetDataFolder :bar:foo                   // Sets CDF to foo in bar current data folder.
SetDataFolder root:foo                   // Sets CDF to foo in the root data folder.
String savedDF= GetDataFolder(1)        // Remember CDF in a string.
NewDataFolder/O/S root:myFolder         // Set CDF to a new data folder.
```

## SetDimLabel

---

```
Variable/G newVariable=1           // Do work in the new data folder.  
SetDataFolder savedDF           // Restore CDF from the string value.
```

### See Also

Chapter II-8, **Data Folders**.

## SetDimLabel

**SetDimLabel** *dimNumber*, *dimIndex*, *label*, *wavelist*

The SetDimLabel operation sets the dimension label or dimension element label to the specified label.

### Parameters

Use *dimNumber*=0 for rows, 1 for columns, 2 for layers and 3 for chunks.

If *dimIndex* is -1, it sets the label for the entire dimension. For *dimIndex*  $\geq$  0, it sets the dimension label for that element of the dimension.

*label* is a name (e.g., time), not a string (e.g., "time").

### See Also

The **GetDimLabel** function. **Dimension Labels** on page II-93 and **Example: Wave Assignment and Indexing Using Labels** on page II-85 for further usage details and examples.

## SetDrawEnv

**SetDrawEnv** [/W=*winName*] *keyword* [=value][, *keyword* [=value]]...

The SetDrawEnv operation sets properties of the drawing environment.

If one or more draw objects are selected in the top window then the SetDrawEnv command will apply only to those objects.

If no objects are selected *and* if the keyword *save* is *not* used *then* the command applies only to the next object drawn.

If no objects are selected *and* if the keyword "save" is used *then* the command sets the environment for all following objects.

Each draw layer has its own draw environment settings.

### Parameters

SetDrawEnv can accept multiple *keyword=value* parameters on one line.

In the following descriptions, (*r*, *g*, *b*) specifies a color. *r*, *g*, and *b* are each a number from 0 to 65535. (0, 0, 0) specifies black. (65535, 65535, 65535) specifies white.

Also note that the abs and rel values for the coordinate keywords "xcoord" and "ycoord" are the literal characters "abs" and "rel"; they are not substitute names for numbers, names, or strings.

<i>arrow=arr</i>	Specifies the arrow head position on lines. <i>arr</i> =0: No arrowhead (default) <i>arr</i> =1: Arrowhead at end. <i>arr</i> =2: Arrowhead at start. <i>arr</i> =3: Arrowhead at start and end.
<i>arrowfat=afat</i>	Sets ratio of arrowhead width to length (default is 0.5).
<i>arrowlen=alen</i>	Sets length of arrowhead in points (default is 10).
<i>arrowSharp=s</i>	Specifies the continuously variable barb sharpness between -1.0 and 1.0. <i>s</i> =1: No barb; lines only. <i>s</i> =0: Blunt (default). <i>s</i> =-1: Diamond.
<i>arrowframe=f</i>	Specifies the stroke outline thickness of the arrow in points (default is <i>f</i> =0 for solid fill).
<i>astyle=s</i>	Specifies which side of the line has barbs relative to a right-facing arrow. <i>s</i> =0: None. <i>s</i> =1: Top.

	<i>s=2</i> : Bottom.
	<i>s=3</i> : Both (default).
<i>dash=dsh</i>	<i>dsh</i> is a dash pattern number between 0 and 17 (see <b>SetDashPattern</b> for patterns). 0 (solid line) is the default.
<i>fillbgc=(r, g, b)</i>	Specifies fill background color. Default is the window's background color.
<i>fillfgc=(r, g, b)</i>	Specifies fill foreground color. The default is white.
<i>fillpat=fpatt</i>	Specifies fill pattern density. <i>fpatt=-1</i> : Erase to background color. <i>fpatt=0</i> : No fill. <i>fpatt=1</i> : 100% (solid pattern, default). <i>fpatt=2</i> : 75% gray. <i>fpatt=3</i> : 50% gray. <i>fpatt=4</i> : 25% gray.
<i>fname="fontName"</i>	Sets font name, default is the default font or the graph font.
<i>fsize=size</i>	Sets text size, default is 12 points.
<i>fstyle=style</i>	Sets text style (same as for the <b>TextBox</b> operation), default is plain.
<i>gedit=flag</i>	Supplies optional edit flag for a group of objects. Use with <i>gstart</i> . <i>flag=0</i> : Select entire group, moveable (default). <i>flag=1</i> : Individual components editable as if not grouped. Allows objects to be grouped by name but still be editable
<i>gname= name</i>	Supplies optional <i>name</i> for an object group. Use with <i>gstart</i> .
<i>gstart</i>	Marks the start of a group of objects.
<i>gstop</i>	Marks the end of a group of objects.
<i>linebgc=(r, g, b)</i>	Sets the line background color. Default is window's background color.
<i>linefgc=(r, g, b)</i>	Sets the line foreground color, default is black.
<i>linepat=patt</i>	Specifies the line pattern/density. <i>patt=1</i> : 100% (solid pattern, default). <i>patt=2</i> : 75% gray. <i>patt=3</i> : 50% gray. <i>patt=4</i> : 25% gray.
<i>linethick=thick</i>	<i>thick</i> is a line thickness $\geq 0$ , default is 1 point.
<i>origin= x0,d0</i>	Moves coordinate system origin to <i>x0,d0</i> . Unlike <i>translate</i> , <i>rotate</i> , and <i>scale</i> , this survives a change in coordinate system and is most useful that way. See <b>Coordinate Transformation</b> .
<i>pop</i>	Pops a draw environment from the stack. Pops should always match pushes.
<i>push</i>	Pushes the current draw environment onto a stack (limited to 10).
<i>rotate= deg</i>	Rotates coordinate system by <i>deg</i> degrees. Does not work with text and pictures. Only makes sense if X and Y coordinate systems are the same. See <b>Coordinate Transformation</b> .
<i>rounding=rnd</i>	Radius for rounded rectangles in points, default is 10.
<i>rsabout</i>	Redefines coordinate system rotation or scaling to occur at the translation point instead of the current origin. To use, combine <i>rotate</i> or <i>scale</i> with <i>translate</i> and <i>rsabout</i> parameters.
<i>save</i>	Stores the current drawing environment as the default environment.
<i>scale= sx,sy</i>	Scales coordinate system by <i>sx</i> and <i>sy</i> . Affects only coordinates — not line thickness or arrow head sizes. See <b>Coordinate Transformation</b> .
<i>textrgb=(r, g, b)</i>	Sets text color, default is black.
<i>textrot=rot</i>	Text rotation in degrees. Supported values are 0, 90, 180, 270, and -90. 0 is normal (default) horizontal left-to-right text,

	90 is vertical bottom-to-top text, etc.
textxjust= <i>xj</i>	Sets horizontal text alignment. <i>xj</i> =0: Left aligned text (default). <i>xj</i> =1: Center aligned text. <i>xj</i> =2: Right aligned text.
textyjust= <i>yj</i>	Sets vertical text alignment. <i>yj</i> =0: Bottom aligned text (default). <i>yj</i> =1: Middle aligned text. <i>yj</i> =2: Top aligned text.
translate= <i>dx,dy</i>	Shifts coordinate system by <i>dx</i> and <i>dy</i> . Units are in the current coordinate system. See <b>Coordinate Transformation</b> .
xcoord=abs	X coordinates are absolute window coordinates (default for all windows <i>except graphs</i> where the default is xcoord=prel). The unit of measurement is pixels if the window is a panel, otherwise they are points. The left edge of the window (or of the printable area in a layout) is at x=0.
xcoord=rel	X coordinates are relative window coordinates. x=0 is at the left edge of the window; x=1 is at the right edge.
xcoord=prel	X coordinates are relative plot rectangle coordinates (graphs only). x=0 is at the left edge of the rectangle; y=1 is at the right edge of the rectangle. This coordinate system ideal for objects that should maintain their size and location relative to the axes, and <i>is the default for graphs</i> .
xcoord= <i>axisName</i>	X coordinates are in terms of the named axis (graphs only).
ycoord=abs	Y coordinates are absolute window coordinates (default for all windows <i>except graphs</i> where the default is ycoord=prel). The unit of measurement is pixels if the window is a panel, otherwise they are points. The top edge of the window (or the of the printable area in a layout) is at y=0.
ycoord=rel	Y coordinates are relative window coordinates. y=0 is at the top edge of the window; y=1 is at the bottom edge.
ycoord=prel	Y coordinates are relative plot rectangle coordinates (graphs only). y=0 is at the top edge of the rectangle; y=1 is at the bottom edge of the rectangle. This coordinate system ideal for objects that should maintain their size and location relative to the axes, and <i>is the default for graphs</i> .
ycoord= <i>axisName</i>	Y coordinates are in terms of the named axis (graphs only).

### Flags

/W= <i>winName</i>	Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy.
--------------------	---

### Coordinate Transformation

The execution order for the translate, rotate, scale, and origin parameters is important. Translation followed by rotation is different than rotation followed by translation. When using multiple keywords in one SetDrawEnv operation, the order in which they are applied is origin, translate, rotate followed by scale regardless of the command order (with the exception of the rsabout parameter). Before using origin with the save keyword, you should use push to save the current draw environment and then use pop after drawing objects using the new origin.

### Examples

Following is a simple example of arrow markers:

```
NewPanel
SetDrawEnv arrow= 1,arrowlen= 30,save
SetDrawEnv arrowsharp= 0.3
DrawLine 61,67,177,31
SetDrawEnv arrowsharp= 1
DrawLine 65,95,181,59
SetDrawEnv astyle= 1
```

```
DrawLine 69,123,185,87
SetDrawEnv arrowframe= 1
DrawLine 73,151,189,115
```

You can position objects in one coordinate system and then draw them in another with the origin keyword. In the following coordinate transformation example, we position arrows in axis units but size them in absolute units.

```
Make/O jack=sin(x/8)
Display jack
SetDrawEnv xcoord=bottom,ycoord=left,save
SetDrawEnv push
SetDrawEnv origin=50,0
SetDrawEnv xcoord=abs,ycoord=abs,arrow=1,arrowlen=20,arrowsharp=0.2,save
DrawLine 0,0,50,0 // arrow 50 points long pointing to the right
DrawLine 0,0,0,50 // arrow 50 points long pointing down
// now let's move over, rotate a bit and draw the same arrows:
SetDrawEnv translate=100,0
SetDrawEnv rotate=30,save
DrawLine 0,0,50,0
DrawLine 0,0,0,50
SetDrawEnv pop
```

Now try zooming in on the graph. You will see that the first pair of arrows always starts at 50 on the bottom axis and 0 on the left axis whereas the second pair is 100 points to the right of the first.

### See Also

Chapter III-3, **Drawing**, and the **TextBox** operation.

## SetDrawLayer

**SetDrawLayer** [/K/W=*winName*] *layerName*

The SetDrawLayer operation makes all future drawing operations use the named layer.

### Parameters

Valid *layerNames* for graphs:

ProgBack	UserBack	ProgAxesUserAxes
ProgFront	UserFront	

Valid *layerNames* for panels and page layouts:

ProgBack	UserBack	ProgFrontUserFront
----------	----------	--------------------

### Flags

/K Kills (erases) the given layer.

/W=*winName* Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

### Details

There are really only two layers for Panels but ProgFront is allowable as an alias for ProgBack. Likewise UserFront is an alias for UserBack.

The back-to-front order of the layers is shown by the Environment pop-up menu if you hold down Option (*Macintosh*) or Alt (*Windows*). This is the Environment pop-up menu for graphs:

### See Also

**Layers** on page III-76.

### SetFileFolderInfo

**SetFileFolderInfo** [ *flags* ] [ *fileOrFolderNameStr* ]

The SetFileFolderInfo operation changes the properties of a file or folder.

#### Parameters

*fileOrFolderNameStr* specifies the file or folder to be changed.

If you use a full or partial path for *fileOrFolderNameStr*, see **Path Separators** on page III-382 for details on forming the path.

Folder paths should not end with single Path Separators. See the **MoveFolder Details** section.

If Igor can not determine the location of the file or folder from *fileOrFolderNameStr* and */P=pathName*, it displays a dialog allowing you to specify the file to be deleted. Use */D* to select a folder in this event, otherwise Igor prompts your for a file.

#### Flags

At least one of the seven following flags is required, or nothing is actually accomplished:

- /CDAT=cdate* Specifies the number of seconds since midnight January 1, 1904 when the file or folder was first created.
- /INV[=inv]* Sets the visibility of a file.  
*inv=0*: File is visible.  
*inv=1*: Default; file is invisible (*Macintosh*) or Hidden (*Windows*).
- /MDAT=mDate* Specifies the number of seconds since midnight January 1, 1904 when the file or folder was modified most recently.
- /RO[=ro]* Sets the read/write state of a file or folder.  
*ro=0*: File or folder is writable.  
*ro=1*: File or folder is locked (default).  
On Windows, set *ro* to any nonzero value to make it read-only. To set the read-only property manually, right-click the file and choose "Properties", then select or deselect the "read-only" checkbox.  
On Macintosh, *ro* is a bitmap of two settings:  
Bit 0: Unlocked.  
Bit 1: "Locked" with the Finder. Only files can be locked this way.  
You set this kind of locking with the Finder's Get Info window by selecting the "Locked" checkbox.  
Bit 2: "File Locked" as with ResEdit. You can't set this kind of locking with the Finder, but applications can. See SetFileFolderInfo.  
Bit 3: Both kinds of locking are set.  
See **Setting Bit Parameters** on page IV-11 for details about bit settings.

If *fileOrFolderNameStr* refers to a file (not a folder), SetFileFolderInfo updates the file properties to reflect values given with the following keywords:

- /CRE8=creatorStr* Sets the four-character creator code string, such as 'IGR0' (Igor Pro creator code). Ignored on Windows, where files have no "creator code"; instead file extensions are "registered" or "owned" by one, and only one, application. You cannot change that ownership from Igor Pro.
- /FTYP=fTypeStr* Sets the four-character file type code, such as 'TEXT' or 'IGsU' (packed experiment). Ignored on Windows. Use **MoveFile** to change the file extension.
- /STA[=st]* Specifies whether the file is a stationery file or not.  
*st=1*: Stationery file (default).  
*st=0*: Normal file.  
Ignored on Windows. Use **MoveFile** to change the file extension.

**Optional Flags**

/D	Uses the Select Folder dialog rather than Open File dialog when <i>pathName</i> and <i>fileOrFolderNameStr</i> do not specify an existing file or folder.
/P= <i>pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
/R[= <i>r</i> ]	Recursively applies change(s) to all files or folders in the folder specified by /P= <i>pathName</i> or <i>fileOrFolderNameStr</i> , and the folder itself: <i>r</i> =0: No recursion. Same as no /R. <i>r</i> =1: Recursively apply changes to files. <i>r</i> =2: Recursively apply changes to folders, including the folder specified by <i>pathName</i> or <i>fileOrFolderNameStr</i> . <i>r</i> =3: Recursively apply changes to both files and folders (default). /R requires /D and a folder specification.
/Z	Prevents procedure execution from aborting if SetFileFolderInfo tries to set information about a file or folder that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort.

**Variables**

SetFileFolderInfo returns information about the file or folder in the following variables:

V_flag	0: File or folder was found. -1: User cancelled the Open File dialog. >0: An error occurred, such as the specified file or folder does not exist.
S_path	File system path of the selected file or folder.

**Examples**

Change the file creator code; no complaint if it doesn't exist:

```
SetFileFolderInfo/Z /CRE8="CWIE", "Macintosh HD:folder:afile.txt"
```

Set the file modification date:

```
Variable mDate= Date2Secs(2000,12,25) + hrs*3600+mins*60+secs  
SetFileFolderInfo/P=myPath/MDAT=(mDate), "afile.txt"
```

Remove read-only property from a folder and everything within it:

```
SetFileFolderInfo/P=myPath/D/R/RO=0
```

**See Also**

The **GetFileFolderInfo**, **ImageFileInfo**, **MoveFile**, and **FStatus** operations. The **IndexedFile**, **date2secs**, and **ParseFilePath** functions.

**SetFormula**

**SetFormula** *waveName*, *expressionStr*

**SetFormula** *variableName*, *expressionStr*

The SetFormula operation binds the named wave, numeric or string variable to the expression or, if the expression is "", unbinds it from any previous expression. In user functions, SetFormula must be used to create dependencies.

**Parameters**

*expressionStr* is a string containing a numeric or string expression, depending on the type of the bound object.

Pass "" (empty string) for *expressionStr* to clear any previous dependency expression associated with the wave or variable.

**Details**

The dependent object (the wave or variable) will depend on the objects referenced in the string expression. The expression will be reevaluated any time an object referred to in the expression is modified.

Besides being set from a string expression this differs from just typing:

```
name := expression
```

in that syntax errors in *expressionStr* are not reported and are not fatal. You end up with a dependency assignment that is marked as needing to be recompiled. The recompilation will be attempted every time an object is created or when the procedure window is recompiled.

## SetIgorHook

---

Use the Object Status dialog in the Misc menu to check up on dependent objects.

### Examples

This command makes the variable `v_sally` dependent on the user-defined function `anotherFunction`, waves `wave_fred` and `wave_sue`, and the system variable `K2`:

```
SetFormula v_sally, "anotherFunction(wave_fred[1]) + wave_sue[0] + K2"
```

This is equivalent to:

```
v_sally := anotherFunction(wave_fred[1]) + wave_sue[0] + K2
```

except that no error will be generated for the `SetFormula` if, for instance, `wave_fred` does not exist.

A string variable dependency can be created by a command such as:

```
SetFormula myStringVar, "note(wave_joe)"
```

observe that *expressionStr* is a string *containing* a string expression, and that:

```
SetFormula myStringVar, note(wave_joe)
```

is not the same thing. In this case the note of `wave_joe` would contain the expression that `myStringVar` would depend on! Also, `wave_joe` would have to exist for Igor to understand the statement.

### See Also

Chapter IV-9, **Dependencies**, and the `GetFormula` function.

## SetIgorHook

**SetIgorHook** [/K/L] [*hookType* = [*procName*]]

The `SetIgorHook` operation calls a user-defined “hook” function during certain events, such as file-opening, cursor-moving, menu selection, Igor startup, or Igor quitting. (The term “hook” is used as in the phrase “to hook into”, meaning to intercept or to attach.)

More than one user-defined function can be called for each event. This avoids the main problem associated with fixed-name functions (see **User-Defined Hook Functions** on page IV-197): multiple procedure files that each define the same nonstatic fixed-name functions (such as `IgorBeforeQuitHook`) causing compilation errors.

### Flags

- /K Removes *procName* from the list of functions called for the *hookType* events.  
If *procName* is not specified all *hookType* functions are removed.  
If *hookType* is not specified all functions are removed for all *hookType* events, returning Igor to the pre-`SetIgorHook` state.
- /L Executes *procName* last. Without /L, a newly added hook function runs before previously registered hook functions.  
A function that has been previously registered with `SetIgorHook` can be moved from being called first to being called last by calling `SetIgorHook` again with /L.  
To move a function from being called last to being called first requires removing the hook function with /K and then calling `SetIgorHook` without /L.

### Parameters

*hookType* Specifies one of the fixed-name hook function names:

**AfterFileOpenHook**  
**AfterWindowCreatedHook**  
**BeforeExperimentSaveHook**  
**BeforeFileOpenHook**  
**IgorBeforeNewHook**  
**IgorBeforeQuitHook**  
**IgorMenuHook**  
**IgorQuitHook**  
**IgorStartOrNewHook**

See the note below about these *hookType* names.

*hookType* is required except with /K.

*procName* Names the user-defined hook function that is called for the *hookType* event.

## Details

The syntax of the user-defined function *procName* varies depending on the *hookType* it is registered for.

For example, a function registered for the AfterFileOpenHook type must have the same syntax as the shown for the **AfterFileOpenHook** on page IV-198.

The *procName* function is called *after* any window-specific hook for these *hookTypes*, and the *procName* function is called *before* any other hook functions previously registered by calling SetIgorHook *unless the /L flag is given*, in which case it still runs after window-specific hook functions, but also *after* all other previously registered hook functions.

The *procName* function should return nonzero to prevent later functions from being called (1 is typical). Returning 0 allows successive functions to be called.

After all the SetIgorHook functions registered for *hookType* have run (and all have returned 0), any static fixed-name hook functions are called and then the (only) fixed-name user-defined hook function, if any, is called. As an example, when a menu event occurs, Igor handles the event by calling the top window's hook function, any SetIgorHook-registered hook functions, and then all of the fixed-named IgorMenuHook functions (first any static IgorMenuHook functions, and then the one-and-only nonstatic **IgorMenuHook** function):

SetWindow event (called first)	SetIgorHook <i>hookType</i> (called second)	User-defined Hook Function(s) (called last)
enableMenu	IgorMenuHook	IgorMenuHook
menu	IgorMenuHook	IgorMenuHook

**Note:** Although you can technically use one of the fixed-name functions, as described in **User-Defined Hook Functions** on page IV-197, for *procName*, the result would be that the function will be called twice: once as a registered named hook function and once as the fixed-named hook function. That is, don't use SetIgorHook this way:

```
SetIgorHook AfterFileOpenHook=AfterFileOpenHook           // NO NO
```

SetIgorHook does not work at Igor start or new experiment time, so instead of SetIgorHook IgorStartOrNewHook, use the global **IgorStartOrNewHook** function (see page IV-206).

## Variables

SetIgorHook returns information in the following variables:

**S\_info** Semicolon-separated list of all current hook names associated with *hookType*, listed in the order in which they are called.

## Examples

This hook function invokes the Export Graphics menu item when Command-C (*Macintosh*) or Ctrl+C (*Windows*) is selected for a graph, preventing the usual Copy.

```
SetIgorHook IgorMenuHook=CopyIsExportHook
```

```
Function CopyIsExportHook(isSelection,menuName,itemName,itemNo,win,wType)
  Variable isSelection
  String menuName,itemName
  Variable itemNo
  String win
  Variable wType
  Variable handledIt= 0
  if( isSelection && wType==1 ) // menu was selected, window is graph
    if( CmpStr(menuName,"Edit")==0 && CmpStr(itemName,"Copy")==0 )
      DoIgorMenu "Edit", "Export Graphics" // dialog instead
      handledIt= 1 // don't call other IgorMenuHook functions.
    endif
  endif
  return handledIt
End
```

To unregister CopyIsExportHook as a hook procedure:

```
SetIgorHook/K IgorMenuHook=CopyIsExportHook // unregister CopyIsExportHook
```

To discover which functions are associated with a *hookType*, use a command such as:

## SetIgorMenuMode

---

```
SetIgorHook IgorMenuHook // inquire about names registered for IgorMenuHook
Print S_info // list of functions
```

To remove (or “unregister”) named hooks:

```
SetIgorHook/K // removes all hook functions for all hookTypes
SetIgorHook/K IgorMenuHook // removes all IgorMenuHook functions
SetIgorHook/K IgorMenuHook=CopyIsExportHook // removes only this hook function
```

### See Also

The **SetWindow** operation and **User-Defined Hook Functions** on page IV-197.

## SetIgorMenuMode

### **SetIgorMenuMode** *MenuNameStr, MenuItemStr, Action*

The SetIgorMenuMode operation allows an Igor programmer to disable or enable Igor’s built-in menus and menu items. This is useful for building applications that will be used by end-users who shouldn’t have access to all Igor’s extensive and confusing functionality.

### Parameters

*MenuNameStr* The name of an Igor menu, like “File”, “Graph”, or “Load Waves”.

*MenuItemStr* The text of an Igor menu item, like “Copy” (in the Edit menu) or “New Graph” (in the Windows menu).

*Action* One of DisableItem, EnableItem, DisableAllItems, or EnableAllItems. DisableItem and EnableItem disable or enable just the single item named by *MenuItemStr* and *MenuNameStr*. If *MenuItemStr* is “”, then the menu itself is disabled. DisableAllItems and EnableAllItems disable and enable all the items in the menu named by *MenuNameStr*.

### Details

All menu names and menu item text are in English. This ensures that code developed for a localized version of Igor will run on all versions. Note that no trailing “...” is used in *MenuItemStr*.

The SetIgorMenuModeProc.ipf procedure file includes procedures and commands that disable or enable every menu and item possible. It is in your Igor Pro folder, in WaveMetrics Procedures:Utilities:. It is not intended to be used as-is. You should make a copy and edit the copy to include just the parts you need.

The text of some items in the File menu changes depending on the type of the active window. In these cases you must pass generic text as the *MenuItemStr* parameter. Use “Save Window”, “Save Window As”, “Save Window Copy”, “Adopt Window” and “Revert Window” instead of “Save Notebook” or “Save Procedure”, etc. Use “Page Setup” instead of “Page Setup For All Graphs”, etc. Use “Print” instead of “Print Graph”, etc.

### See Also

The **DoIgorMenu** operation.

## SetIgorOption

**SetIgorOption** [*mainKeyword*,] *keyword= value*

**SetIgorOption** [*mainKeyword*,] *keyword= ?*

The SetIgorOption operation makes unusual and temporary changes to Igor Pro’s behavior. This operation is not compilable and you will need to use the **Execute** operation to use it in a user function. The details of the syntax depend on the application and are documented where the alternate behaviors are described. In most cases the current value of a setting can be read using the *keyword=?* syntax. Simple numeric options are stored in *V\_flag* and color options are stored in *V\_Red*, *V\_Green*, and *V\_Blue*. The settings last for the life of the Igor session.

### See Also

**Syntax Coloring** on page III-339 for some usage examples; **Macintosh and LAPACK Library** on page III-140; **Limitations of Independent Modules** on page IV-41; **Conditional Compilation** on page IV-68; **Pre-Carbon Page Setup Records** on page III-381. **MarkPerfTestTime** operation.

## SetMarquee

**SetMarquee** [/W=*winName*] *left, top, right, bottom*

The SetMarquee operation creates a marquee on the target graph or layout window or the specified window or subwindow. The *left, top, right, bottom* coordinates are the same as those returned by the GetMarquee operation (screen units measured in points).

The optional axis modes supported by GetMarquee are not supported by SetMarquee.

### Flags

/W=*winName* Specifies the named window or subwindow. When omitted, action will affect the active window or subwindow.  
When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

### See Also

The **GetMarquee** operation.

## SetProcessSleep

**SetProcessSleep** *sleepTicks*

The SetProcessSleep operation determines how much time Igor will give to background tasks or other Macintosh applications executing in the background. This operation does nothing on Windows.

### Parameters

*sleepTicks* is the amount of time given to background tasks in sixtieths of a second. *sleepTicks* values between 0 and 60 are valid.

### Details

Igor starts up with *sleepTicks* = 1. Use 0 to give Igor maximum time, use a larger number to give other applications more time.

Background tasks are used mainly by data acquisition programs.

### See Also

**Background Task** on page IV-211 and the **SetBackground** operation.

## SetRandomSeed

**SetRandomSeed** *seed*

The SetRandomSeed operation seeds the random number generator used for the **ennoise** and **gnoise** functions. Use SetRandomSeed if you need "random" numbers that are reproducible. If you don't use SetRandomSeed, the random number generator is initialized using the system clock when Igor starts. This almost guarantees that you will never get the same sequence twice unless you use SetRandomSeed.

### Parameters

*seed* should be a number from 0 to 1. For any given *seed*, **ennoise** or **gnoise** generates a particular sequence of pseudorandom numbers. Calling SetRandomSeed with a *seed* of your choice restarts and repeats the sequence.

### See Also

The **ennoise** and **gnoise** functions.

## SetScale

**SetScale** [/I/P] *dim, num1, num2* [, *unitsStr*] ,*waveName* [, *waveName*]...

**SetScale** *d, num1, num2* [, *unitsStr*], *waveName* [, *waveName*]...

The SetScale operation sets the dimension scaling or the data full scale for the named waves.

### Parameters

The first parameter *dim* must be one of the following:

Character	Signifies
d	Data full scale.
t	Scaling of the chunks dimension (t scaling).

## SetVariable

---

Character	Signifies
x	Scaling of the rows dimension (x scaling).
y	Scaling of the columns dimension (y scaling).
z	Scaling of the layers dimension (z scaling).

If setting the scaling of any dimension ( $x$ ,  $y$ ,  $z$ , or  $t$ ),  $num1$  is the starting index value — the scaled index for the first point in the dimension. The meaning of  $num2$  changes depending on the /I and /P flags. If you use /P, then  $num2$  is the delta value — the difference in the scaled index from one point to the next. If you use /I,  $num2$  is the “ending value” — the index value for the last element in the dimension. If you use neither flag,  $num2$  is the “right value” — the index value that the element *after the last element in the dimension* would have.

These three methods are just three different ways to specify the two scaling values, the starting value and the delta value, that are stored for each dimension of each wave.

If setting the data full scale ( $d$ ), then  $num1$  is the nominal minimum and  $num2$  is the nominal maximum data value for the waves. The data full scale values are not used. They serve only to document the minimum and maximum values the waves are expected to attain. No flags are used when setting the data full scale.

The *unitsStr* parameter is a string that identifies the natural units for the  $x$ ,  $y$ ,  $z$ ,  $t$ , or data values of the named waves. Igor will use this to automatically label graph axes. This string must be one to 49 characters such as “m” for meters, “g” for grams or “s” for seconds. If the waves have no natural units you can pass “” for this parameter.

### Flags

At most one flag is allowed, and then only if dimension scaling (not data full scale) is being set:

- /I Inclusive scaling.  $num2$  is the ending index — the index value for the very last element in the dimension.
- /P Per-point scaling.  $num2$  is the delta index value — the difference in scaled index value from one element to the next.

### Details

SetScale will not allow the delta scaling value to be zero. If you execute a SetScale command with a delta value of zero, it will set the delta value to 1.0.

If you do not use the /P flag, SetScale converts  $num1$  and  $num2$  into a starting index value and a delta index value. If you call SetScale on a dimension with fewer than two elements, it does this conversion as if the dimension had two elements.

Prior to Igor Pro 3.0, Igor supported only 1D waves. “SetScale x” was used to set the scaling for the rows dimensions and “SetScale y” was used to set the data full scale. With the addition of multidimensional waves, “SetScale y” is now used to set the scaling of the columns dimension and “SetScale d” is used to set the data full scale. For backward compatibility, “SetScale y” on a 1D wave sets the data full scale.

When setting the dimension scaling of a numeric wave, you can omit the *unitsStr* parameter. Igor will set the wave’s scaling but not change its units. However, when setting the dimension scaling of a text wave, you must supply a *unitsStr* parameter (use “” if the wave has no units). If you don’t, Igor will think that the text wave is the start of a string expression and will attempt to treat it as the *unitsStr*.

**Note:** Prior to Igor Pro 3.0, SetScale with no wave names would set the default characteristics for waves made subsequently with the Make command. In Igor Pro 2.0, this behavior was considered obsolete and the manual warned that it was not recommended. As of Igor Pro 3.0 SetScale will still set the default x scaling, but will beep and put up a warning dialog. In future versions, SetScale without a wave name will not work. At present, you cannot set the default y, z, or t scaling with SetScale.

### See Also

The **Make** command. For an explanation of waves and dimension scaling, see **Changing Dimension and Data Scaling** on page II-70.

## SetVariable

**SetVariable** [/Z] *ctrlName* [*key* [= *value*]][, *key* [= *value*]]...

The SetVariable operation creates or modifies a SetVariable control in the target window.

A SetVariable control sets the value of a global numeric or string variable when you type or click in the control. As of Igor Pro version 4.04, a SetVariable can also be attached to a specific point in a wave.

For information about the state or status of the control, use the **ControlInfo** operation.

### Parameters

*ctrlName* is the name of the SetVariable control to be created or changed.

*key* is one of the following parameters:

activate	Activates the control and selects the text that sets the value. Use <b>ControlUpdate</b> to deactivate the control and deselect the text.
appearance={ <i>kind</i> [, <i>platform</i> ]}	Sets the appearance of the control. <i>platform</i> is optional. Both parameters are names, not strings. <i>kind</i> can be one of <code>default</code> , <code>native</code> , or <code>os9</code> . <i>platform</i> can be one of <code>Mac</code> , <code>Win</code> , or <code>All</code> . See <b>Button</b> and <b>DefaultGuiControls</b> for more appearance details.
bodyWidth= <i>width</i>	Specifies an explicit size for the body (nontitle) portion of a SetVariable control. By default (bodyWidth=0), the body portion is the amount left over from the specified control width after providing space for the current text of the title portion. If the font, font size or text of the title changes, then the body portion may grow or shrink. If you supply a bodyWidth>0, then the body is fixed at the size you specify regardless of the body text. This makes it easier to keep a set of controls right aligned when experiments are transferred between Macintosh and Windows, or when the default font is changed.
disable= <i>d</i>	Sets user editability of the control. <i>d</i> =0: Normal. <i>d</i> =1: Hide. <i>d</i> =2: No user input.
font=" <i>fontName</i> "	Sets the font used to display the value of the variable, e.g., font="Helvetica".
format= <i>formatStr</i>	Sets the numeric format of the displayed value, e.g., format="%g". Not used with string variables. Never use leading text or the "%W" formats, because Igor reads the value back without interpreting the units. For a description of <i>formatStr</i> , see the <b>printf</b> operation.
frame= <i>f</i>	<i>f</i> =0: Value unframed. <i>f</i> =1: Value framed (default).
fsize= <i>s</i>	Sets the size of the type used to display the variable's value.
fstyle= <i>fs</i>	<i>fs</i> is a binary coded number with each bit controlling one aspect of the font style as follows: bit 0: Bold. bit 1: Italic. bit 2: Underline. bit 3: Outline (Macintosh only). bit 4: Shadow (Macintosh only). See <b>Setting Bit Parameters</b> on page IV-11 for details about bit settings.
help={ <i>helpStr</i> }	Sets the help for the control. The help text is limited to a total of 255 characters. On Macintosh, the help appears if you turn Igor Tips on. On Windows, the help for the first 127 characters or up to the first line break appears in the status line. If you press F1 while the cursor is over the control, you will see the entire help text. You can insert a line break by putting "\r" in a quoted string.
labelBack=( <i>r,g,b</i> ) or 0	Specifies the background fill color for labels. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535. The default is 0, which uses the window's background color.
limits={ <i>low,high,inc</i> }	Sets the limits of the allowable values ( <i>low</i> and <i>high</i> ) for the variable. <i>inc</i> sets the amount by which the variable is incremented if you click the control's up/down arrows. This applies to numeric variables, not to string variables. If <i>inc</i> is zero then the up/down arrows will not be drawn.
live= <i>l</i>	<i>l</i> =0: Update only after variable changes (default).

## SetVariable

---

	<i>l</i> = 1: Update as variable changes.
<code>noedit=<i>val</i></code>	<code>noedit=1</code> prevents the user from clicking (or tabbing into) a <code>SetVariable</code> control to directly edit its value. This is useful when you want to make a string read-only or when you want to restrict a numeric setting to those available only via the control's up or down arrow buttons. <code>noedit=0</code> reactivates user editing.
<code>noproc</code>	No procedure is to execute when the control's value is changed.
<code>pos={<i>left,top</i>}</code>	Sets position of control in pixels.
<code>proc=<i>procName</i></code>	Sets the procedure to execute when the control's value is changed.
<code>rename=<i>newName</i></code>	Gives control a new name.
<code>size={<i>width,height</i>}</code>	Sets width of control in pixels. <i>height</i> is ignored.
<code>title=<i>titleStr</i></code>	Sets title of control to the specified string expression. The title is displayed to the left of the control. If <i>titleStr</i> is empty (" "), the name of the controlled variable is displayed as the title. Use <code>title=" "</code> (put a space within the quotation marks) to create a "blank" title.
<code>userdata(<i>UDName</i>)=<i>UDStr</i></code>	Sets the unnamed user data to <i>UDStr</i> . Use the optional ( <i>UDName</i> ) to specify a named user data to create.
<code>userdata(<i>UDName</i>)+=<i>UDStr</i></code>	Appends <i>UDStr</i> to the current unnamed user data. Use the optional ( <i>UDName</i> ) to append to the named <i>UDStr</i> .
<code>value=<i>varName</i></code>	Sets the numeric or string variable or wave to be controlled. If wave, the point is specified using standard bracket notation with either a numeric point number or a row label, for example: <code>value=awave[ 4 ]</code> or <code>value=awave[ %aLabel ]</code> . You may also use a matrix wave and specify a column index in addition to the row index.
<code>win=<i>winName</i></code>	Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed. When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy.

### Flags

`/Z` No error reporting.

### Details

The target window must be a graph or panel.

The procedure, which may be a function *or* a macro, has the format:

```
Function procName(ctrlName,varNum,varStr,varName) : SetVariableControl
    String ctrlName
    Variable varNum          // value of variable as number
    String varStr            // value of variable as string
    String varName           // name of variable
    ...
End
```

The "`: SetVariableControl`" puts the procedure in the Procedure pop-up menu in the `SetVariable` Control dialog.

The action procedure for a `SetVariable` control can also use a predefined structure `WMSetVariableAction` as a parameter to the function. The control will use this more efficient method when the function properly matches the structure prototype for a `SetVariable` control, otherwise it will use the old-style method.

A `SetVariable` action procedure using a structure has the format:

```
Function newActionProcName(SV_Struct)
    STRUCT WMSetVariableAction &SV_Struct
    ...
End
```

For a SetVariable control, the `WMSetVariableAction` structure has members as described in the following table:

**WMSetVariableAction Structure Members**

Member	Description										
<code>char ctrlName[MAX_OBJ_NAME+1]</code>	Control name.										
<code>char win[MAX_WIN_PATH+1]</code>	Host (sub)window.										
<code>STRUCT Rect winRect</code>	Local coordinates of host window.										
<code>STRUCT Rect ctrlRect</code>	Enclosing rectangle of the control.										
<code>STRUCT Point mouseLoc</code>	Mouse location.										
<code>Int32 eventCode</code>	Event that executed the procedure.										
	<table border="1"> <thead> <tr> <th>eventCode</th> <th>Event</th> </tr> </thead> <tbody> <tr> <td>-1</td> <td>Control being killed</td> </tr> <tr> <td>1</td> <td>Mouse up</td> </tr> <tr> <td>2</td> <td>Enter key</td> </tr> <tr> <td>3</td> <td>Live update</td> </tr> </tbody> </table>	eventCode	Event	-1	Control being killed	1	Mouse up	2	Enter key	3	Live update
eventCode	Event										
-1	Control being killed										
1	Mouse up										
2	Enter key										
3	Live update										
<code>Int32 eventMod</code>	Bitfield of modifiers. See description of <code>MODIFIERS: flags</code> for <code>SetWindow</code> under <b>Unnamed Hooks</b> on page V-505.										
<code>String userdata</code>	Primary (unnamed) user data. If this changes, it is written back automatically.										
<code>Int32 isStr</code>	TRUE for a string variable.										
<code>double dval</code>	Numeric value of variable.										
<code>char sval[MAXCMDLEN]</code>	Value of variable as a string.										
<code>char vName[MAX_OBJ_NAME+2+MAX_OBJ_NAME+4+1]</code>	Name of variable or wave. Dimension labels can be used for waves.										
<code>WAVE svWave</code>	Valid if using wave.										
<code>Int32 rowIndex</code>	Row index for a wave, unless <code>rowLabel</code> is not null.										
<code>char rowLabel[MAX_OBJ_NAME+1]</code>	Wave row label.										
<code>Int32 colIndex</code>	Column index for a wave, unless <code>colLabel</code> is not null.										
<code>char colLabel[MAX_OBJ_NAME+1]</code>	Wave column label.										

Action functions should respond only to documented `eventCode` values. Other event codes may be added along with more fields. Although the return value is not currently used, action functions should always return zero.

The constants used to specify the size of structure `char` arrays are internal to Igor Pro and may change.

### Examples

Executing the commands:

```
Variable/G globalVar=99
SetVariable setvar0 size={120,20}
SetVariable setvar0 font="Helvetica", value=globalVar
```

creates this SetVariable control: `globalVar`

### See Also

The `printf` operation for an explanation of `formatStr`, and **Set Variable** on page III-348.

## SetVariableControl

---

The **ControlInfo** operation for information about the control. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **GetUserData** operation for retrieving named user data.

## SetVariableControl

### **SetVariableControl**

SetVariableControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined SetVariable control. See **Procedure Subtypes** on page IV-149 for details.

## SetWaveLock

### **SetWaveLock** *lockVal*, *waveList*

The SetWaveLock operation locks a wave or waves and protects them from modification. Such protection is not absolute, but it should prevent most common attempts to change or kill a wave.

#### **Parameters**

*lockVal* can be 0, to unlock, or 1, to lock the wave(s).

*waveList* is a list of waves or it can be `allInCDF` to act on all waves in the current data folder.

## SetWindow

### **SetWindow** *winName* [, *keyword* = *value*]...

The SetWindow operation sets the window note and user data for the named window or subwindow. SetWindow can also set hook functions for a base window or exterior subwindow (interior subwindows not supported).

#### **Parameters**

*winName* can be a window or subwindow name. It can also be the keyword `kwTopWin` to specify the topmost graph, panel, layout, table, or notebook window.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

<code>hide = <i>h</i></code>	Hides or unhides widows or subwindows. <i>h</i> =0: Unhides a subwindow or base window <i>h</i> =1: Hides a subwindow or base window. <i>h</i> =2: Unhides without restoring minimized windows ( <i>Windows</i> only). When un hiding subwindows, you should combine with <code>needUpdate=1</code> if conditions require the subwindow to be redrawn since the window was hidden.
<code>hook=<i>procName</i></code>	Sets the name of the function called when certain events happen. Use <code>SetWindow hook=\$" "</code> to specify no hook function. See <b>Unnamed Hooks</b> for further details.
<code>hook(<i>hName</i>)=<i>procName</i></code>	Defines a named hook <i>hName</i> and sets the name of the function called when certain events happen. <i>hName</i> can be any legal name. Named hooks are called before any unnamed hooks. The <i>procName</i> hook function must use the <code>WMWinHookStruct</code> structure as a parameter. See <b>Named Hooks</b> for further details.
<code>hookcursor=<i>number</i></code>	Uses the cursor specified by <code>hookcursor</code> in the interior of the window if hook is specified, if <code>hookevents</code> bit 1 is set, and if <code>hookcursor</code> is nonzero. Currently, there are 27 cursors.
<code>hookevents=<i>flags</i></code>	Bitfield of flags to enable certain events: bit 0: Mouse button clicks. bit 1: Mouse moved events. bit 2: Cursor moved events. To set bit 0 and bit 1 (mouse clicks and mouse moved), use $2^0+2^1 = 1+2 = 3$ for <i>flags</i> . Use 7 to also enable cursor moved events. See <b>Setting Bit Parameters</b> on page IV-11 for details about bit settings.
<code>needUpdate= <i>n</i></code>	Marks a window as needing an update ( <i>n</i> =1) or takes no action ( <i>n</i> =0).
<code>note=<i>noteStr</i></code>	Sets the window note to <i>noteStr</i> , replacing any existing note.
<code>note+=<i>noteStr</i></code>	Appends <i>noteStr</i> to current contents of the window note.

`userdata=UDStr`

`userdata(UDName)=UDStr`

Sets the window or subwindow user data to *UDStr*. Use the optional (*UDName*) to specify a named user data to create.

`userdata+=UDStr`

`userdata(UDName)+=UDStr`

Appends *UDStr* to the current window or subwindow user data. Use the optional (*UDName*) to append to the named user data.

### Unnamed Hooks

The hook function is called when various window events take place. The reason for the hook function call is stored as an event code in the hook function's *infoStr* parameter. This is used for advanced user controls.

The hook function is not called during experiment creation or load time so as to prevent the hook function from failing because the experiment is not fully recreated.

The hook function has the following syntax:

```
Function procName(infoStr)
  String infoStr
  String event= StringByKey("EVENT",infoStr)
  ...
  return statusCode           // 0 if nothing done, else 1
End
```

*infoStr* is a string which will contain a semicolon separated list of *key:value* pairs:

<b>EVENT:</b> <i>eventKey</i>	<i>eventKey</i> identifies the event:
<code>activate</code>	Window has just been activated.
<code>copy</code>	Copy menu item has been selected.
<code>deactivate</code>	Window has just been deactivated.
<code>enablemenu</code>	Menus are being built and enabled.
<code>hide</code>	Window or subwindows about to be hidden.
<code>kill</code>	Window is being killed.
<code>killVote</code>	Window is about to be killed. Return 2 to prevent that, otherwise return 0 (see <b>Notes on Events 14-17 and 2</b> ).
<code>menu</code>	A built-in menu item has been selected.
<code>modified</code>	A modification to the graph has been made (graphs only).
<code>moved</code>	Window has just been moved.
<code>renamed</code>	Window has just been renamed. The previous name is available under the OLDWINDOW key.
<code>resize</code>	Window has just been resized.
<code>show</code>	Window or subwindows is about to be unhidden.
<code>subwindowKill</code>	One of the window's subwindows is about to be killed.

**Note:** The copy event introduced in Igor 4.03 has been replaced by the menu event. If the corresponding *hookevents* flag bits are set, then the following events will also be reported. If the hook function returns a nonzero value then Igor will not do its usual processing.

`mousedown` When the mouse button is clicked (bit 0).

`mousemove` Called continuously as the mouse is moved (bit 1).

`mouseup` Mouse button is released (bit 0).

**HCSPEC:** *winName* Absolute path of the window or subwindow. See **Subwindow Command Concepts** on page III-92.

**MODIFIERS:** *flags* Bits set based on state of certain keys:

bit 0: Set if mouse button is down.

bit 1: Set if Shift is down.

## SetWindow

---

- bit 2: Set if Option (*Macintosh*) or Alt (*Windows*) is down.
- bit 3: Set if Command (*Macintosh*) or Ctrl (*Windows*) is down.
- bit 4: Contextual menu click: right-click or Control-click (*Macintosh*), or right-click (*Windows*).

See **Setting Bit Parameters** on page IV-11 for details about bit settings.

**OLDWINDOW: winName** Previous name of the window or subwindow (for renamed event). Not the old absolute path *hcSpec*, just the name. WINDOW and HCSPEC contain the new name and new *hcSpec*.

**WINDOW: winName** Name of the window.

Returning a value of 2 for the kill message will prevent Igor from killing the associated window.

The modified event (added in Igor 4.05) is issued only when a graph updates (See **DoUpdate**, **PauseUpdate**, and **ResumeUpdate**). Most changes to the graph are accompanied by the **modified** event, but not all: changing an annotation will not trigger the event, nor will adding, removing, or modifying a control or showing or hiding the drawing tools while using the /A flag. The modified event is not sent while a trace is being dragged or when the values of a trace's wave change (unless one the trace's axes is autoscaled). However, changing an axis range or indeed changing almost anything about axes or showing or hiding the info pane will send the modified event (only one event per graph update). When in doubt, use a print statement to determine when the event is sent.

If mouse events are reported then the following will also be present:

**MOUSEX: x pixel** X coordinate in pixels of the mouse.

**MOUSEY: y pixel** Y coordinate in pixels of the mouse.

**TICKS: time** Time event happened.

Note that a mouseup event may or may not correspond to a previous mousedown. If the user clicks in the window, drags out and releases the button then the mouseup event will be missing. If the user clicks in another window, drags into this one and then releases then a mouseup will be sent that had no previous mousedown.

In the case of mousedown or mousemoved messages, a nonzero return value will skip normal processing of the message. This is most useful with mousedown.

The **cursormoved** event not reported if Option (*Macintosh*) or Alt (*Windows*) is held down. It is also not reported unless the **hookevents** bit 2 is set.

If the **cursormoved** event is reported then the following will also be present:

**CURSOR: A - J** Name of the cursor that moved.

**TNAME: traceName** Name of the trace the cursor is attached to (invalid if **ISFREE=1**).

**ISFREE: free** 1 if the cursor is "free" (not attached to a trace), 0 if it is attached to a trace or image.

**POINT: pt** Point number of *traceName* if not a free cursor. If the cursor is attached to an image, *pt* is the row number of the image.

If a free cursor, *pt* is the fraction of the plot width, 0 being the left edge of the plot area, and 1 being the right edge.

**YPOINT: yPt** Column number if the cursor is attached to an image, NaN if attached to a trace.

If a free cursor, *yPt* is the fraction of the plot height, 0 being the top edge, and 1 being the bottom edge.

If the a menu event is reported then the following will also be present:

**MENUNAME: menuStr** Name of menu (in English) as used by **SetIgorMenuMode**.

**MENUITEM: itemStr** Text of menu item as used by **SetIgorMenuMode**.

(The **enablemenu** event does not pass **MENUNAME** or **MENUITEM**).

The **menu** and **enablemenu** messages are not sent during when drawing tools are in use in a graph or layout or when waves are being edited in a graph.

Returning a value of 0 for the **enablemenu** message is recommended, though its value is (currently) ignored.

You can use the **SetIgorMenuMode** operation to alter the enable state of Igor's built-in menus in a way you find appropriate for the window. If you do this, usually you will also handle the menu message and perform your idea of an appropriate action.

**Note:** Dynamic user-defined menus (see **Dynamic Menu Items** on page IV-91) are built and enabled by using string functions in the menu definitions.

Returning a value of 0 for any menu message allows Igor to perform the normal action. Returning any other value (1 is commonly used) does not perform the normal action.

See the user function description with **IgorMenuHook** on page IV-204 for details on the sequence of menu building, enabling, and handling.

**Note:** Returning a value of 2 for the copy menu item message is no longer handled specially by Igor Pro 5. In Igor Pro 4 it invoked the Export Graphics dialog. The second example below shows the new way of doing this.

### Named Hooks

When using named window hooks, your hook function must use a predefined structure **WMWinHookStruct** as a parameter. This structure will provide your function with information about the status of various window events. See **Structures in Functions** on page IV-61.

The function prototype used with a named hook has the format:

```
Function myWindowHook(H_Struct)
    STRUCT WMWinHookStruct &H_Struct
    <code to test and process events>
    ...
    return statusCode          // 0 if nothing done, else 1
End
```

The **WMWinHookStruct** structure has members as described in the following tables:

#### Base **WMWinHookStruct** Structure Members

Member	Description
char winName[MAX_PATH_LENGTH+1]	hcspec of the affected (sub)window.
STRUCT Rect winRect	Local coordinates of the affected (sub)window.
STRUCT Point mouseLoc	Mouse location.
double ticks	Tick count when event happened.
Int32 eventCode	See see <b>Event Code</b> table on page V-508.
char eventName[31+1]	Name-equivalent of eventCode, see <b>Event Code</b> table on page V-508. Added in Igor 5.03.
Int32 eventMod	Bitfield of modifiers. See description for <b>MODIFIERS: flags</b> .

#### Members of **WMWinHookStruct** Structure Used with menu Code

Member	Description
char menuName[255+1]	Name of menu (in English) as used by <b>SetIgorMenuMode</b> .
char menuItem[255+1]	Text of the menu item as used by <b>SetIgorMenuMode</b>

**Members of `WMWinHookStruct` Structure Used with `cursormoved` Code**

Member	Description
<code>char traceName[MAX_OBJ_NAME+1]</code>	The name of the trace or image to which the moved cursor is attached or which supplies the X (and Y) values. Can be "" if the cursor is free.
<code>char cursorName[2]</code>	Cursor name A through J.
<code>double pointNumber</code>	Point number of the trace or the X (row) point number of the image where the cursor is attached.  If the cursor is "free", <code>pointNumber</code> is actually the fractional relative <i>xValue</i> as used in the <b>Cursor/F/P</b> command.
<code>double yPointNumber</code>	Valid only when the cursor is attached to a two-dimensional item such as an image, contour, or waterfall plot, or when the cursor is free.  If attached to an image, contour, or waterfall plot, <code>yPointNumber</code> is the Y (column) point number of the image where the cursor is attached.  If the cursor is "free", <code>yPointNumber</code> is actually the fractional relative <i>yValue</i> as used in the <b>Cursor/F/P</b> command.
<code>Int32 isFree</code>	Has value of 1 if the cursor is not attached to anything, or value of 0 if it is attached to a trace, image, contour, or waterfall.

**User-Modifiable Members of `WMWinHookStruct` Structure**

Member	Description
<code>Int32 doSetCursor</code>	Set TRUE to change cursor to that specified by <code>cursorCode</code> .
<code>Int32 cursorCode</code>	Standard cursor as set by <code>hookcursor=number</code> .

**Members of `WMWinHookStruct` Used with `renamed` Code**

Member	Description
<code>char oldWinName[MAX_OBJ_NAME+1]</code>	Old name of the window or subwindow. Not the absolute path <i>hcSpec</i> , just the name.

**Members of `WMWinHookStruct` Structure Used with `keyboard` Code**

Member	Description
<code>Int32 keycode</code>	ASCII value of key struck. Function keys are not available but navigation keys are translated to specific values and will be the same on Macintosh and Windows.

When determining the state of the `eventCode` member of the `WMWinHookStruct` structure, the various `eventCode` and `eventName` values you use in your window hook function are defined as:

Event Code	eventName	Notes
0	"Activate"	
1	"Deactivate"	
2	"Kill"	
3	"Mousedown"	

Event Code	eventName	Notes
4	"Mousemoved"	
5	"Mouseup"	
6	"Resize"	
7	"Cursormoved"	See <b>Cursors — Moving Cursor Calls Function</b> on page IV-220.
8	"Modified"	
9	"Enablemenu"	
10	"Menu"	
11	"Keyboard"	Not sent to unnamed window hook functions.
12	"moved"	
13	"renamed"	
14	"subwindowKill"	One of the window's subwindows is about to be killed.
15	"hide"	The window or one of its subwindows is about to be hidden.
16	"show"	The window or one of its subwindows is about to be unhidden.
17	"killVote"	Window is about to be killed. Return 2 to prevent the window from being killed, otherwise return 0.  <b>Note:</b> Don't delete data structures during this event, use killVote only to decide whether the window kill should actually happen. Delete data structures in the kill event. See <b>Notes on Events 14-17 and 2</b> .

Named hooks are called for all events and ignore any hookevents settings. You should respond only to events you know about, and return a nonzero value only when you want to cut short any further event handing by any other hooks or by Igor.

The principal reason to allow multiple hooks is for add-on packages to be able to add their processing without fear of wiping out any existing hook functions. Because of the possibilities for confusion, you should take great care when using multiple hook functions.

#### Notes on Events 14-17 and 2

The actions caused by these events potentially affect multiple subwindows.

If you kill a subwindow, the root window's hook function(s) receives a subwindowKill event for that subwindow and any child subwindows.

If you kill a root window, the root window's hook function(s) receives a subwindowKill event for each child subwindow, and then the root window's hook function(s) receive a kill event.

Likewise, hiding and showing windows can result in subwindows being hidden or shown. In each case, the window hook function receives a hide or show event for each affected window or subwindow.

The winName member of WMWinHookStruct will be set to the full subwindow path of the subwindow that is affected.

Exterior subwindows are a special case because they are subwindows, but you can attach a hook function to an exterior subwindow. The hook function attached to the root window does not receive events affecting exterior subwindows. To handle subwindowKill, hide, or show events when an exterior subwindow is killed, hidden, or shown as a result of killing, hiding, or showing its parent window, you must have a hook function attached to the exterior subwindow.

As a further subtlety, the hook function(s) attached to an exterior subwindow will receive a subwindowKill event if the exterior subwindow is killed as a result of killing the parent window. But it will receive a regular kill event if it is killed directly. Normal subwindows always receive only subwindowKill events.

The kill-related events are sent in this order when a window or subwindow is killed:

## SetWindow

---

1. A killVote event is sent to the root window's hook function(s). If any hook function returns 2, no further events are generated and the window is not killed.
2. If the window is not a subwindow and wasn't created with /K=k the standard window close dialog appears. If the close is cancelled, the window is not killed, the window will receive an activate event when the dialog is dismissed, and no further events are generated. Otherwise, proceed to step 3.
- 3) If the window being killed has subwindows, starting from the bottom-most subwindow and working back toward the window being killed:
  - 3a. If the subwindow is a graph or panel, action procedures for controls contained in the subwindow are called with event -1, "control being killed".
  - 3b. The root window's hook function(s) receive a subwindowKill event for the subwindow. If any hook function returns 1, no further subwindow hook events or control being killed events are sent, but the window killing process continues.Steps 3a and 3b are repeated for each subwindow until the window or subwindow being killed is reached.
4. If the killed window is a root window, a kill event is sent to the root window's hook function(s). If any hook function returns 2, no further events are generated and the window is not killed. This method of preventing a window from closing is to be avoided: use the killVote event or the window-equivalent of NewPanel/K=2.

There are several ways to prevent a window being killed. You might want to do this in order to enforce use of a Done or Do It button, or to prevent killing a control panel while some hardware action is taking place.

The best method is to use /K=2 when creating the window (see **Display** or **NewPanel**). Then the only way to kill the window is via the DoWindow/K command, or KillWindow command. In general, you would provide a button that kills the window after checking for any conditions that would prevent it.

The KillVote event is more flexible but harder to use. It gives your code a chance to decide whether or not killing is allowed. This means the user can close and kill the window with the window close box when it is allowed.

Returning 2 for the window kill event is not recommended. If you have old code that uses this method, we strongly recommend changing it to return 2 for the killVote event. New code should never return 2 for the kill event.

Events 14-17 were added to Igor Pro version 6.02.

### Example

Following is an example using a named hook to set the cursor as the mouse is moved horizontally across the bottom half of the window:

```
static constant kUHC_mousemoved=4
Function MyWinHook(s)
  STRUCT WMWinHookStruct &s
  Variable rval= 0
  switch(s.eventCode)
    case kUHC_mousemoved:
      if( s.mouseLoc.v > ((s.winRect.top+s.winRect.bottom)/2) )
        s.doSetCursor= 1
s.cursorCode= round(27*(s.mouseLoc.h - s.winRect.left)/(s.winRect.right-s.winRect.left))
        rval= 1 // we have taken over this event
      endif
      break
  EndSwitch
  return rval
End
Function test()
  Make/O jack=x
  Display jack
  SetWindow kwTopWin, hook(testhook)= MyWinHook
End
```

This window hook invokes the Export Graphics menu item when Command-C (*Macintosh*) or Ctrl+C (*Windows*) is selected for a graph, preventing Igor from performing the usual Copy.

```
Display myData
SetWindow kwTopWin hook=CopyIsExportHook
Function CopyIsExportHook(infoStr)
  string infoStr
  string event= StringByKey("EVENT", infoStr)
```

```

string win= StringByKey("WINDOW",infoStr)
variable handledIt= 0
strswitch(event)
  case "menu":
    String menuName= StringByKey("MENUNAME", infoStr)
    String itemName= StringByKey("MENUITEM", infoStr)
    if( CmpStr(menuName,"Edit")==0 && CmpStr(itemName,"Copy")==0 )
      DoIgorMenu "Edit", "Export Graphics" // dialog instead
      handledIt= 1
    endif
  break
endswitch
return handledIt
End

```

This example uses a window hook and button action procedure to implement a panel dialog with a Done button such that the panel can't be closed by clicking the panel's close widget, but can be closed by the Done button's action procedure:

```

Proc ShowDialog()
  PauseUpdate; Silent 1 // building window...
  NewPanel/N=Dialog/W=(225,105,525,305) as "Dialog"
  Button done,pos={119,150},size={50,20},title="Done"
  Button done,proc=DialogDoneButtonProc
  TitleBox warning,pos={131,83},size={20,20},title=""
  TitleBox warning,anchor=MC,fColor=(65535,16385,16385)
  SetWindow Dialog hook(dlog)=DialogHook, hookevents=2
EndMacro

Function DialogHook(s)
  STRUCT WMWinHookStruct &s
  Variable statusCode= 0

  strswitch( s.eventName )
  case "killVote":
    TitleBox warning win=$s.winName, title="Press the Done button!"
    Beep
    statusCode=2 // prevent panel from being killed.
    break
  case "mousemoved": // to reset the warning
    TitleBox warning win=$s.winName, title=""
    break
  endswitch

  return statusCode
End

Function DialogDoneButtonProc(ba) : ButtonControl
  STRUCT WMButtonAction &ba
  switch( ba.eventCode )
  case 2: // mouse up turn off the named window hook
    SetWindow $ba.win hook(dlog)="$"
    // kill the window AFTER this routine returns
    Execute/P/Q/Z "DoWindow/K "+ba.win // kill the window AFTER this routine returns
    break
  endswitch
  return 0
End

```

### See Also

The **GetWindow**, **SetIgorHook**, and **SetIgorMenuMode** operations and **AxisValFromPixel**, **NumberByKey**, **PopupContextualMenu**, and **TraceFromPixel** functions. The **GetUserData** operation for retrieving named user data.

## ShowIgorMenus

**ShowIgorMenus** [*MenuNameStr* [, *MenuNameStr*] ...

The ShowIgorMenus operation shows the named built-in menus or, if none are explicitly named, shows all built-in menus in the menu bar.

User-defined menus attached to built-in menus are also affected by this operation.

### Parameters

*MenuNameStr*      The name of an Igor menu, like "File", "Data", or "Graph".

## ShowInfo

---

### Details

See **HideIgorMenus** for details.

### See Also

Chapter IV-5, **User-Defined Menus**.

The **HideIgorMenus**, **DoIgorMenu**, and **SetIgorMenuMode** operations.

## ShowInfo

**ShowInfo** [ /W=*winName* ]

The ShowInfo operation puts an information box on the target or named graph. The information box contains cursors and readouts of values associated with waves in the graph.

### Flags

/W=*winName*      Displays info box in the named window.

### See Also

**Info Box and Cursors** on page II-265.

The **HideInfo** operation.

## ShowTools

**ShowTools** [ /A/W=*winName* ] [ *toolName* ]

The ShowTools operation puts a tool palette for drawing along the left hand side of the target or named graph or control panel, and optionally activates the named tool.

### Flags

/A                      Sizes window automatically to make extra room for the tool palette. This preserves the proportion and size of the actual graph area.

/W=*winName*          Shows tool palette in the named window. This must be the first flag specified when used in a Proc or Macro or on the command line.

### Parameters

If you specify a *toolName* (which can be one of: normal, arrow, text, line, rect, rrect, oval, or poly) the named tool is activated. Specifying the “normal” tool has the same effect as issuing the GraphNormal command for a graph that has the drawing tools selected.

### Details

The activated tool is not highlighted until the top graph or control panel becomes the topmost (activated) window. Use DoWindow/F to bring a window to the top (or “front”).

### See Also

The **DoWindow**, **GraphNormal**, **GraphWaveDraw**, **GraphWaveEdit**, and **HideTools** operations.

## sign

**sign**(*num*)

The sign function returns -1 if *num* is negative or 1 if it is not negative.

## Silent

**Silent** *num*

The Silent operation enables or disables the display of macro commands in the command line as they are executed.

### Parameters

If *num* is one, the display of macro commands is disabled. If *num* is zero, it is enabled.

When executed from the command line, “Silent 100” activates a compatibility mode that can run legacy macro code containing old-style comments, which use | instead of //, without causing errors. To exit this mode, execute “Silent 101” on the command line. Also see **Comments** on page IV-2.

If you create procedure files for use by others and you want to use the new logic operations such as || that require that Silent 101 be in effect, then you can specify

`#pragma rtGlobals=2`  
in place of the normal `rtGlobals=1`.

If your procedure file is included in an experiment running in compatibility mode (Silent 100) then an alert dialog will allow the user to switch the experiment to the new syntax. However, keep in mind that when the procedures are recompiled in the new mode, the user's other procedures may not compile due to obsolete use of the vertical bar (|) as a comment character.

#### Details

Macros run faster if this display is disabled. If Silent is used in a macro its effect ends when the macro ends.

This has no effect in user-defined functions. During execution of a user-defined function, Igor does not display anything in the command line.

Commands sent to Igor Pro from another program via PPC or Apple events are normally logged into the history area. You can turn off the logging of these commands with the Silent operation. See also **The Silent Option** on page IV-84.

#### See Also

The **PauseUpdate** operation and **rtGlobals**.

## sin

### **sin(*angle*)**

The sin function returns the sine of *angle* which is in radians. In complex expressions, *angle* is complex, and `sin(angle)` returns a complex value.

## sinc

### **sinc(*num*)**

The sinc function returns `sin(num)/num`. The sinc function returns 1.0 when *num* is zero. *num* must be real.

## sinh

### **sinh(*num*)**

The sinh function returns the hyperbolic sine of *num*. In complex expressions, *num* is complex, and `sinh(num)` returns a complex value.

## Sleep

### **Sleep [*flags*] *timeSpec***

The Sleep operation puts Igor to sleep for a while. After the while is up, Igor continues execution. You could use this, for example, to print a graph late at night, when the load on your printer is light.

#### Parameters

The format of *timeSpec* depends on which flags, if any, are present.

If no flags are present, then *timeSpec* is in *hh:mm:ss* format and specifies the number of elapsed hours, minutes and seconds to sleep.

#### Flags

/A *timeSpec* is an absolute time in 24 hour format (e.g., 16:00:00).

/A/W Wait until tomorrow if absolute time has passed.

/B Stop sleeping if the user clicks the mouse button.

/C=*cursor* Controls what kind of cursor to display during sleep.

*cursor*=-1: No cursor change.

*cursor*=0: Hour glass (default).

*cursor*=1: Arrow.

*cursor*=2: "Click".

*cursor*=<any other value>: watch.

/Q Continue executing the procedure containing the Sleep operation even if Command-period (Macintosh) or Ctrl+Break (Windows) was pressed.

## Slider

---

`/S` *timeSpec* is a numeric expression in seconds.  
`/T` *timeSpec* is a numeric expression in ticks (about 1/60 of a second).

### Details

The Sleep operation does *not* let the user choose menus, move cursors, run procedures, draw in graphs, or do any other interactive task.

Normally *timeSpec* specifies an amount of elapsed time. If the `/A` flag is present, then *timeSpec* is an absolute time when sleep is to end. If the specified absolute time has already passed, no sleep occurs unless you also use `/W`, which makes it wait until tomorrow.

If you specify time in hh:mm:ss format, you can also specify the time indirectly through a string variable. See the examples.

You can end sleep by pressing Command-period (*Macintosh*) or Ctrl+Break (*Windows*). Normally when you do this, it aborts any procedure that is running. However, if you use the `/Q` flag, the procedure continues running normally.

### Examples

These examples assume the current time is 4 pm:

```
Sleep 00:01:30           // sleeps for 1 minute, 30 seconds
Sleep/A 23:30:00        // sleeps until 11:30 PM
Sleep/A 03:00:00        // doesn't sleep at all because time is past
Sleep/A/W 03:00:00      // sleeps until 3 AM tomorrow
String str1= "03:00:00" // put wakeup call time in string
Sleep/A/W $str1          // sleeps until 3 AM tomorrow
Sleep/B/C=2/S/Q 60      // sleep 60 seconds, or until user clicks,
                        // and keep going (don't abort)
```

## Slider

**Slider** [`/Z`] *controlName* [*key* [= *value*]][, *key* [= *value*]]...

The Slider operation creates or modifies a Slider control in the target window.

A Slider control sets or displays a single numeric value. The user can adjust the value by dragging a thumb along the length of the Slider.

For information about the state or status of the control, use the **ControlInfo** operation.

### Parameters

*ctrlName* is the name of the Slider control to be created or changed.

*key* is one of the following parameters:

`appearance={kind [, platform]}`

Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

*kind* can be one of `default`, `native`, or `os9`.

*platform* can be one of `Mac`, `Win`, or `All`.

**Note:** The Slider control reverts to `os9` appearance on Macintosh if `thumbColor` isn't the default blue (0,0,65535).

See **Button** and **DefaultGuiControls** for more appearance details.

`disable=d`

Sets user editability of the control.

`d=0:` Normal.

`d=1:` Hide.

`d=2:` Draw in gray state; disable control action.

`font="fontName "`

Sets the font used to display the tick labels, e.g., `font="Helvetica"`.

`fsize=s`

Sets the size of the type for tick mark labels.

`help={helpStr}`

Sets the help for the control. The help text is limited to a total of 255 characters. On Macintosh, the help appears if you turn Igor Tips on. On Windows, the help for the first 127 characters or up to the first line break appears in the status line. If you press F1 while the cursor is over the control, you will see the entire help text. You can insert a line break by putting `"\r"` in a quoted string.

<code>limits={low,high,inc}</code>	<code>low</code> sets left or bottom value, <code>high</code> sets right or top value. Use <code>inc=0</code> for continuous or use desired increment between stops.
<code>live=l</code>	<code>l=0</code> : Update only after mouse is released. <code>l=1</code> : Update as slider moves (default).
<code>noproc</code>	Specifies that no procedure is to execute when the control's value is changed.
<code>pos={left,top}</code>	Sets position of control in pixels.
<code>proc=procName</code>	Specifies the procedure to execute when the control's thumb is moved by the user.
<code>rename=newName</code>	Gives control a new name.
<code>side=s</code>	<code>s=0</code> : Thumb is blunt. <code>s=1</code> : Thumb points right or down (default). <code>s=2</code> : Thumb points up or left.
<code>size={width,height}</code>	Sets width or height of control in pixels. <code>height</code> is ignored if <code>vert=0</code> and <code>width</code> is ignored if <code>vert=1</code> .
<code>thumbColor=(r,g,b)</code>	Sets dominant foreground color of thumb. <code>r</code> , <code>g</code> , and <code>b</code> are integers from 0 to 65535. Only the hue and saturation are used. Therefore (0,1000,0) is the same tint of green as (0,10000,0).
<code>ticks=t</code>	<code>t=0</code> : No ticks. <code>t=1</code> : Number of ticks is calculated from limits (no ticks drawn if calculated value is less than 2 or greater than 100). Default value. <code>t&gt;1</code> : <code>t</code> is the number of ticks distributed between the start and stop position. Ticks are labeled using the same automatic algorithm used for graph axes. Use negative tick values to force ticks to not be labeled. Ticks are shown on the side specified by the <code>side</code> keyword and are not drawn if <code>side=0</code> .
<code>tkLblRot= deg</code>	Rotates tick labels in multiples of 90 degrees only.
<code>userdata(UDName)=UDStr</code>	Sets the unnamed user data to <code>UDStr</code> . Use the optional ( <code>UDName</code> ) to specify a named user data to create.
<code>userdata(UDName)+=UDStr</code>	Appends <code>UDStr</code> to the current unnamed user data. Use the optional ( <code>UDName</code> ) to append to the named <code>UDStr</code> .
<code>userTicks={tvWave,tlblWave}</code>	User-defined tick positions and labels. <code>tvWave</code> contains the tick positions, and text wave <code>tlblWave</code> contains the labels. See <b>ModifyGraph (axes) userticks</b> for more info. Overrides normal ticking specified by <code>ticks</code> keyword.
<code>value=v</code>	<code>v</code> is the new value for the Slider.
<code>variable= var</code>	Sets the variable ( <code>var</code> ) that the slider will update. Unlike <code>SetVariable</code> controls, it is not necessary to connect a Slider to a variable — you can get a Slider's value using the <b>ControlInfo</b> operation.
<code>vert=v</code>	Set vertical ( <code>v=1</code> ; default) or horizontal ( <code>v=0</code> ) orientation of the slider.
<code>win=winName</code>	Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed. When identifying a subwindow with <code>winName</code> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy.

**Flags**

`/Z` No error reporting.

**Details**

The target window must be a graph or panel.

The format of the action procedure (set by the `proc` keyword) that will be called as the user drags the Slider's thumb is:

```
Function MySliderProc(name, value, event)
    String name           // name of this slider control
    Variable value       // value of slider
```

## Slider

```
Variable event          // bit field:bit 0:value set; 1:mouse down,  
                        // 2:mouse up, 3:mouse moved  
return 0                // other return values reserved  
End
```

If you use negative ticks to suppress automatic labeling, you can label tick marks using drawing tools (panels only).

The action procedure for a Slider control can also use a predefined structure `WMSliderAction` as a parameter to the function. The control will use this more efficient method when the function properly matches the structure prototype for a Slider control, otherwise it will use the old-style method.

A Slider action procedure using a structure has the format:

```
Function newActionProcName(S_Struct)  
    STRUCT WMSliderAction &S_Struct  
    ...  
End
```

For a Slider control, the `WMSliderAction` structure has members as described in the following table:

**WMSliderAction Structure Members**

Member	Description
<code>char ctrlName[MAX_OBJ_NAME+1]</code>	Control name.
<code>char win[MAX_WIN_PATH+1]</code>	Host (sub)window.
<code>STRUCT Rect winRect</code>	Local coordinates of host window.
<code>STRUCT Rect ctrlRect</code>	Enclosing rectangle of the control.
<code>STRUCT Point mouseLoc</code>	Mouse location.
<code>Int32 eventCode</code>	Event that caused the procedure to execute. Sets bit fields: bit 0: value set. bit 1: mouse down. bit 2: mouse up. bit 3: mouse moved.  When the control is about to be killed, <code>eventCode</code> is set to -1.
<code>Int32 eventMod</code>	Bitfield of modifiers. See description of <code>MODIFIERS: flags</code> for <b>SetWindow</b> under <b>Unnamed Hooks</b> on page V-505.
<code>String userdata</code>	Primary (unnamed) user data. If this changes, it is written back automatically.
<code>double curval</code>	Value of slider.

Action functions should respond only to documented `eventCode` values. Other event codes may be added along with more fields. Although the return value is not currently used, action functions should always return zero.

The constants used to specify the size of structure `char` arrays are internal to Igor Pro and may change.

### Examples

```
Function SliderExample()  
    NewPanel /W=(150,50,501,285)  
    Variable/G var1  
    Execute "ModifyPanel cbRGB=(56797,56797,56797)"  
    SetVariable setvar0,pos={141,18},size={122,17},limits={-Inf,Inf,1},value=var1  
    Slider foo,pos={26,31},size={62,143},limits={-5,10,1},variable=var1  
    Slider foo2,pos={173,161},size={150,53}  
    Slider foo2,limits={-5,10,1},variable=var1,vert=0,thumbColor=(0,1000,0)  
    Slider foo3,pos={80,31},size={62,143}  
    Slider foo3,limits={-5,10,1},variable=var1,side=2,thumbColor=(1000,1000,0)  
    Slider foo4,pos={173,59},size={150,13}  
    Slider foo4,limits={-5,10,1},variable=var1,side=0,vert=0  
    Slider foo4,thumbColor=(1000,1000,1000)  
    Slider foo5,pos={173,90},size={150,53}
```

```
Slider foo5,limits={-5,10,1},variable= var1,side=2,vert=0
Slider foo5,ticks=5,thumbColor=(500,1000,1000)
End
```

**See Also**

The **ControlInfo** operation for information about the control. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **GetUserData** operation for retrieving named user data.

## Slow

**Slow ticks**

The Slow operation slows down execution of macros for debugging purposes.

**Parameters**

*ticks* is in units of 1/60 second. A value of 30 is about right to allow you to read the macro command lines as they are executed. Slow 0 resumes normal macro execution.

**Details**

This has no effect in user-defined functions.

## Smooth

**Smooth** [*flags*] *num*, *waveName* [, *waveName*...]

The Smooth operation smooths the named waves using binomial (Gaussian) smoothing, boxcar (sliding average) smoothing, Savitzky-Golay (polynomial) smoothing, or running-median filtering.

**Parameters**

*num* is the number of smoothing operations to be applied for binomial smoothing or the number of points in the smoothing window for boxcar, Savitzky-Golay, and running-median smoothing.

Each *waveName* is smoothed in-place, overwriting the values with the smoothed result. *waveName* may be a floating point or integer wave.

If *waveName* contains NaNs, the results are undefined. (The **Loess** operation and the Interpolate XOP can fill in NaNs).

**Flags**

- /B [=*b*]                    Invokes boxcar smoothing algorithm. If given, *b* specifies the number of passes to use when smoothing the data with smoothing factor *num* (box width). The number of passes can be any value between 1 and 32767.
- /DIM=*d*                    Specifies the wave dimension to smooth.  
*d*=-1:    Treats entire wave as 1D (default).  
For *d*=0, 1, ..., operates along rows, columns, etc.
- /E=*endEffect*             Determines how to handle the ends of the wave (*w*) when fabricating missing neighbor values.  
*endEffect*=0:    Bounce method (default). Uses *w*[*i*] in place of the missing *w*[-*i*] and *w*[*n-i*] in place of the missing *w*[*n+i*].  
*endEffect*=1:    Wrap method. Uses *w*[*n-i*] in place of the missing *w*[-*i*] and vice versa.  
*endEffect*=2:    Zero method. Uses 0 for any missing value.  
*endEffect*=3:    Fill method. Uses *w*[0] in place of the missing *w*[-*i*] and *w*[*n*] in place of the missing *w*[*n+i*].
- /EVEN [=evenAllowed]     Specifies the smoothing increment for boxcar smoothing (/B). Values are:  
0:            Increments even values of *num* to the next odd value. Default when /EVEN omitted.  
1:            Uses even values of *num* for boxcar smoothing despite the half-sample shifting this introduces in the smoothed output (prior to version 6, this shift was prevented). Same as /EVEN alone.
- /F [=f]                    Selects the boxcar or multipass binomial smoothing method:  
*f*=0:        Slow, but accurate, method (default).

	<i>f=1</i> : Fast method. Same as /F alone.
<i>/M=threshold</i>	Invokes running-median smoothing and specifies an absolute numeric threshold used to optionally replace “outliers”. Points that differ from the central median by an amount exceeding <i>threshold</i> are replaced, either with the <i>replacement</i> value specified by /R, or otherwise with the median value. Special <i>threshold</i> values are: 0: Replace all values with running-median values or the <i>replacement</i> value. (NaN): Replace only NaN input values with running-median values or the <i>replacement</i> value. The smoothing factor <i>num</i> is the number of points in the smoothing window used to compute each median.
<i>/R=replacement</i>	Specifies the value that replaces input values that exceed the central median by <i>threshold</i> (requires /M). <i>threshold</i> can be any value (including NaN or ±Inf if <i>waveName</i> is floating point).
<i>/S=sgOrder</i>	Invokes Savitzky-Golay smoothing algorithm and specifies the smoothing order. <i>sgOrder</i> must be either 2 or 4.

### Details

For binomial smoothing, use no flags (other than /DIM, /E, and /F) and a *num* value from 1 to 32767.

The binomial smooth algorithm automatically switches to a nearly equivalent (but *much* faster) multipass box smooth at smooth factor of 50. The original algorithm can be used when you set global variable `V_doOrigBinomSmooth=1` in the root data folder. To get the pre-Igor Pro 5pX behavior you also need to add the /F flag.

The /F (fast boxcar smoothing) algorithm creates small errors when the data has a large offset. For some data sets you may want to subtract the mean of the data before smoothing and add it back in afterwards.

The binomial smoothing algorithm does not detect and ignore NaNs in the input data.

For boxcar smoothing, use the /B flag and a *num* value from 1 to 32767.

For  $num < 2$ , no smoothing is done.

If *num* is even and /EVEN is not specified, *num* is incremented to the next (odd) integer.

If *num* is even and /EVEN is specified, each smoothed output is formed from one more previous value than future values.

The boxcar smoothing algorithm detects and ignores NaNs in the input data. If *num* is less than the number of NaNs near the output point, then the result is NaN. Otherwise the average of the non-NaN neighboring points is used to compute the smoothed result.

For Savitzky-Golay smoothing, use the /S flag and an odd *num* value from 5 to 25. An even value for *num* returns an error. If *sgOrder=4*, then *num=5* gives no smoothing at all so *num* should be at least 7.

The Savitzky-Golay smoothing algorithm does not detect and ignore NaNs in the input data.

For running-median smoothing, use the /M flag and a *num* value from 1 to 32767. If *num* is even, the median is the average of the two middle values. When *num* is 1, no smoothing is done

Use /M=0 to replace all values with the median over the smoothing window or use /M=*threshold*/R=(NaN) to replace outliers with NaNs.

Use /M=(NaN) to replace only NaN input values with the running-median values or the *replacement* value.

The running-median smoothing algorithm detects and ignores NaNs in the input data. If *num* is less than the number of NaNs near the output point, then the result is NaN. Otherwise the median of the non-NaN neighboring points is used to compute the smoothed result.

These smoothing algorithms compute the output value for a given point using each point's neighbors. Except for running-median smoothing, each algorithm combines neighboring points before and after the point being smoothed. At the start or end of a wave some points will not have enough neighbors so some method for fabricating neighbor values must be implemented. The /E flag specifies the method.

The running-median filter, however, ignores /E. At each end of the data fewer values are included in the median calculation, so that values “beyond” the end of data are not needed.

The first output value is the median of `wave[0, floor((num-1)/2)]`. For example, if *num* = 7, then the first output value is the median of `wave[0]`, `wave[1]`, `wave[2]`, and `wave[3]`. Because that is an even number

of points, the median is the average of the two middle values. Continuing the example, if the values were 3, 1, 7, and 5, the two middle values are 3 and 5. The computed median would be  $(3+5)/2=4$ .

### Examples

Box smoothing example:

```
Make/N=100 wv; Display wv
wv=gnoise(1)
Smooth/B/E=3 3,wv      // output[p] = average of wv[p-1], wv[p] and wv[p+1]
                       // /E=3 causes wv[0] = (w[0]+w[0]+w[1])/3
                       // and wv[n-1] = (w[n-2]+w[n-1]+w[n-1])/3
```

Demonstrate the impulse response of Savitzky-Golay Smoothing:

```
Make/O/N=100 wv
wv= p==50           // 1 at center of wave, 0 elsewhere; an impulse
SetScale/P x, 0, 1/1000, "s", wv           // 1000 Hz sampling rate
Smooth/S=2 5,wv
Display wv
ModifyGraph mode=8,marker=19
FFT/MAG/DEST=fftMag wv
Display fftMag
```

Replace NaN with median:

```
Make/O/N=100 data= enoise(1)>.9 ? NaN : sin(x/8)           // signal with NaNs
Duplicate/O data, dataMedian
Smooth2/M=(NaN) 5, dataMedian           // replace (only) NaNs with 5-point median
```

### SmoothCustom

**SmoothCustom** [**/E=endEffect**] *coefsWaveName*, *waveName* [, *waveName*]...

**Note:** SmoothCustom is obsolete. Use the **FilterFIR** operation instead. For multidimensional data use the **MatrixConvolve** or **MatrixFilter** operations.

The SmoothCustom operation smooths waves by convolving them with *coefsWaveName*.

#### Parameters

*coefsWaveName* must be single or double floating point, must not be one of the destination *waveNames*, must not be complex.

*waveName* is a numeric destination wave that is overwritten by the convolution of itself and *coefsWaveName*.

#### Flags

*/E=endEffect* End effect method, a value between 0 and 3. See the **Smooth** operation for a description of the */E* flag.

#### Details

The convolution is in the time domain. That is, the FFT is not employed. For this reason the length of *coefsWaveName* should be small or small in comparison to the destination waves.

SmoothCustom presumes that the middle point of *coefsWaveName* corresponds to the delay = 0 point. The "middle" point number =  $\text{trunc}(\text{numpts}(\text{coefsWaveName}-1)/2)$ . *coefsWaveName* usually contains the two-sided impulse response of a filter, and contains an odd number of points. This is the type of wave created by FilterFIR.

SmoothCustom ignores the X scaling of all the waves.

The SmoothCustom operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details.

## Sort

**Sort** [**/A/C/R**] *sortKeyWaves*, *sortedWaveName* [, *sortedWaveName*]...

The Sort operation sorts the *sortedWaveNames* by rearranging their Y values to put the data values of *sortKeyWaves* in order.

#### Parameters

*sortKeyWaves* is either the name of a single wave, to use a single sort key, or the name of multiple waves in braces, to use multiple sort keys.

All waves must be of the same length.

The *sortKeyWaves* must not be complex.

#### Flags

*/A* Alphanumeric sort. When *sortKeyWaves* includes text waves, the normal sorting places "wave1" and "wave10" before "wave9". Use */A* to sort the number portion numerically, so that "wave9" is sorted before "wave10".

*/C* Case-sensitive sort. When *sortKeyWaves* includes text waves, the sort is case-insensitive unless you use the */C* flag to make it case-sensitive.

*/R* Reversed sort; sort from largest to smallest.

#### Details

*sortKeyWaves* are not actually sorted unless they also appear in the list of destination waves.

The sort algorithm does not maintain the relative position of items with the same key value.

#### Examples

```
Sort/R myWave,myWave // sorts myWave in decreasing order
Sort xWave,xWave,yWave // sorts x wave in increasing order,
// corresponding yWave values follow.
Make/O/T myWave={"1st","2nd","3rd","4th"}
Make/O key1={2,1,1,1} // places 2nd, 3rd, 4th before 1st.
Make/O key2={0,1,3,2} // arranges 2nd, 3rd, 4th as 2nd, 4th, 3rd.
Sort {key1,key2},myWave // sorts myWave in increasing order by key1.
// For equal key1 values, sorted by key2.
```

```

// Result is myWave={"2nd","4th","3rd","1st"}
Make/O/T tw={"w1","w10","w9","w-2.1"}
Sort/A tw,tw // sorts tw in increasing number-aware order:
// Result is tw={"w-2.1","w1","w9","w10"}

```

### See Also

The **MakeIndex**, **IndexSort**, and **Reverse** operations. See **Sorting** on page III-132.

## SortList

**SortList(listStr [, listSepStr [, options]])**

The SortList function returns *listStr* after sorting it according to the default or *listSepStr* and *optionsStr* parameters. *listStr* should contain items separated by the *listSepStr* character, such as "the first item;second item;".

Use SortList to sort the items in a string containing a list of items separated by a single character, such as those returned by functions like **TraceNameList** or **WaveList**, or a line of text from a delimited text file.

*listSepStr* and *options* are optional; their defaults are ";" and 0 (alphabetic sort), respectively.

### Details

*listStr* is treated as if it ends with a *listSepStr* even if it doesn't. The returned list will always have an ending *listSepStr* character.

Only the first character of *listSepStr* is used. If *listSepStr* is "" then the default of ";" is used.

*options* is a literal number which controls the sorting method. *options* is one of:

- 0: Default sort (ascending case-sensitive alphabetic ASCII sort).
- 1: Descending sort.
- 2: Numeric sort.
- 4: Case-insensitive sort.
- 8: Case-sensitive alphanumeric sort using system script.
- 16: Case-insensitive alphanumeric sort that sorts wave0 and wave9 before wave10.

or a bitwise combination of the above with the following restriction: only one of 2, 4, 8, or 16 may be specified. The legal values are thus 0, 1, 2, 3, 4, 5, 8, 9, 16, and 17. Other values will produce undefined sorting criteria.

### Examples

```

// alphabetic sorts
Print SortList("b;c;a;") // prints "a;b;c;"
Print SortList("you,me,i",",",4) // prints "i,me,you,"
Print SortList("9,93,91,33,15,3",",",0) // prints "15,3,33,9,91,93,"
Print SortList("Zx;abc;All;",",",0) // prints "All;Zx;abc;"
Print SortList("Zx;abc;All;",",",8) // prints "abc;All;Zx;"
Print SortList("w9;w10;w02;",",",16) // prints "w02;w9;w10;"

// numeric sorts
Print SortList("9,93,91,33,15,3",",",2) // prints "3,9,15,33,91,93,"
// (reversed)
Print SortList("9,93,91,33,15,3",",",3) // prints "93,91,33,15,9,3,"

```

## SoundInRecord

**SoundInRecord [/Z] wave**

The SoundInRecord operation records audio input at the sample rate obtained from the wave's X scaling and for the number of points determined by the length of the wave. The recording is done synchronously.

Number type of wave must be 8-bit integer or 16-bit integer. The sound input driver is told to record at that number of bits. If 16 bit recording is not supported by the hardware, the sound driver may return an error but more likely will simply translate 8 to 16.

To record in stereo, provide a 2 column wave. (The software is designed to handle any number of channels but has not been tested on more than 2.)

## SoundInSet

---

### Flags

*/Z* Errors are not fatal. *V\_flag* is set to zero if no error, else nonzero if error.

### Details

SoundInRecord requires a computer with sound inputs. Several sample experiments using sound input can be found in your Igor Pro Folder in the Examples folder.

**Note:** Mac OS X (at least up to 10.3) appears to require stereo and 16 bits.

### See Also

The **SoundInSet**, **SoundInStartChart**, and **SoundInStatus** operations.

## SoundInSet

**SoundInSet** [*/Z*][*gain=g, agc=a*]

The SoundInSet operation is used to setup the input device for recording.

### Parameters

SoundInSet can accept multiple *keyword =value* parameters on one line.

*agc=a* Turns automatic gain control mode on (*a=1*) or off (*a=0*). Will generate an error if device does not support setting *agc*. Use **SoundInStatus** to check or use */Z* flag to make errors nonfatal.  
*Windows:* This is not supported and *V\_SoundInAGC* from the **SoundInStatus** command always returns -1.

*gain=g* Sets input gain, 0 is lowest gain and 1 is highest. Will generate an error if device does not support setting *gain*. Use **SoundInStatus** to check or use */Z* flag to make errors nonfatal.  
*Windows:* SoundInSet attempts to adjust the master gain of the sound input device but not all sound cards have a master gain. If *V\_SoundInGain* from the **SoundInStatus** command returns -1, you will have to use your sound card software to adjust the input gain for the particular input source you are using. On some cards there are separate line-in and microphone-in sources.

### Flags

*/Z* Errors are not fatal. *V\_flag* is set to zero if no error, else nonzero if error.

### Details

SoundInSet requires a computer with sound inputs. Several sample experiments using sound inputs are in your Igor Pro Folder in the Examples folder.

### See Also

The **SoundInRecord**, **SoundInStartChart**, and **SoundInStatus** operations.

## SoundInStartChart

**SoundInStartChart** [*/Z*] *buffersize, destFIFOname*

The SoundInStartChart operation starts audio data acquisition into the given FIFO.

### Parameters

*buffersize* is the number of bytes to allocate for the interrupt time buffer which then feeds into the given Igor named FIFO *destFIFOname*. The FIFO must be set up with the correct number of channels and with either 16- or 8-bit integer number type. The sample rate is read from the FIFO also, so that also needs to be correct.

### Flags

*/Z* Errors are not fatal. *V\_flag* is set to zero if no error, else nonzero if error.

### Details

SoundInStartChart requires a computer with sound inputs. Several sample experiments using sound inputs are in your Igor Pro Folder in the Examples folder.

**Note:** Mac OS X (at least up to 10.3) appears to require stereo and 16 bits.

### See Also

The **SoundInRecord**, **SoundInSet**, **SoundInStatus** and **SoundInStopChart** operations, and **FIFOs and Charts** on page IV-208.

## SoundInStatus

### SoundInStatus

The SoundInStatus operation creates and sets a set of variables and strings with information about the current sound input device. The variable `V_flag` is set to an error code and will be zero if the device is available. If not then none of the following are valid.

Variables	Contents
<code>S_SoundInName</code>	String with name of device.
<code>V_SoundInAGC</code>	Automatic gain control on or off (1 or 0). This is an optional item and if the current device does not support AGC then <code>V_SoundInAGC</code> will be set to -1.
<code>V_SoundInChansAv</code>	Available number of channels (e.g., 1 for mono, 2 for stereo).
<code>V_SoundInGain</code>	Current input gain. Ranges from 0 (lowest) to 1. This is an optional item and if the current device does not support gain then <code>V_SoundInGain</code> will be set to -1.
<code>V_SoundInSampSize</code>	Bits set depending on number of bits in a sample available: Bit 0 set if can do 8 bits, bit 1 set if can do 16 bits.
<code>W_SoundInRates</code>	Wave containing sample rate info: if point zero contains zero then points 1 and 2 contain the lower and upper limits of a continuous range else point zero contains the number of discrete rates which follow in the wave. The usual rates are 11025, 22050 and 44100 Hz.

### See Also

The **SoundInRecord**, **SoundInSet**, and **SoundInStartChart** operations.

## SoundInStopChart

### SoundInStopChart [ /Z ]

The SoundInStopChart operation stops audio data acquisition started by SoundInStartChart.

### Flags

/Z Errors are not fatal. `V_flag` is set to zero if no error, else nonzero if error.

### Details

SoundInStopChart requires a computer equipped with sound input hardware.

Audio data acquisition also stops automatically when an experiment is closed.

### See Also

The **SoundInStartChart** and **SoundInStatus** operations.

## SpecialCharacterInfo

### SpecialCharacterInfo(*notebookNameStr*, *specialCharacterNameStr*, *whichStr*)

The SpecialCharacterInfo function returns a string containing information about the named special character in the named notebook window.

### Parameters

*notebookNameStr* is the name of a notebook or "" for the top visible notebook.

*specialCharacterNameStr* is the name of a special character in the notebook.

*whichStr* identifies the information item you want. Because SpecialCharacterInfo can return several items that may contain semicolons, it does not return a semicolon-separated keyword-value list like other info functions. Instead it returns just one item as specified by *whichStr*.

### Details

Here are the supported values for *whichStr*.

## SpecialCharacterInfo

---

Keyword	Returned Action Information												
FRAME	<table><thead><tr><th>FRAME</th><th>Kind</th></tr></thead><tbody><tr><td>0</td><td>None</td></tr><tr><td>1</td><td>Single</td></tr><tr><td>2</td><td>Double</td></tr><tr><td>3</td><td>Triple</td></tr><tr><td>4</td><td>Shadow</td></tr></tbody></table>	FRAME	Kind	0	None	1	Single	2	Double	3	Triple	4	Shadow
FRAME	Kind												
0	None												
1	Single												
2	Double												
3	Triple												
4	Shadow												
LOC	Paragraph and character position (e.g., 1,3).												
SCALING	Horizontal and vertical scaling in units of one tenth of a percent (e.g., 1000,1000).												
TYPE	Special character type is: Picture, Graph, Table, Layout, Action, ShortDate, LongDate, AbbreviatedDate, Time, Page, TotalPages, or WindowTitle.												

---

The remaining keywords apply to notebook action characters only. If the specified special character is not a notebook action character, "" is returned.

Keyword	Returned Action Information														
BGRGB	Background color in RGB format (e.g., 65535,65534,49151).														
COMMANDS	Command string.														
ENABLEBGRGB	1 if the action's background color is enabled, 0 if not.														
HELPTXT	Help text string.														
IGNOREERRORS	0 or 1.														
LINKSTYLE	0 or 1.														
PADDING	The value of the left, right, top, bottom and internal padding properties, in that order (e.g, 4,4,4,4,8).														
PICTURE	1 if the action has a picture, 0 if not.														
PROCPICNAME	The name of the action Proc Picture or "" if none.														
QUIET	0 or 1.														
SHOWMODE	<table><thead><tr><th>SHOWMODE</th><th>Displayed</th></tr></thead><tbody><tr><td>1</td><td>Title only</td></tr><tr><td>2</td><td>Picture only</td></tr><tr><td>3</td><td>Picture below title</td></tr><tr><td>4</td><td>Picture above title</td></tr><tr><td>5</td><td>Picture to the left of title</td></tr><tr><td>6</td><td>Picture to the right of title</td></tr></tbody></table>	SHOWMODE	Displayed	1	Title only	2	Picture only	3	Picture below title	4	Picture above title	5	Picture to the left of title	6	Picture to the right of title
SHOWMODE	Displayed														
1	Title only														
2	Picture only														
3	Picture below title														
4	Picture above title														
5	Picture to the left of title														
6	Picture to the right of title														
TITLE	Title string.														

---

If *whichStr* is an unknown keyword, SpecialCharacterInfo returns "" but does not generate an error.

### Examples

```
Function PrintSpecialCharacterInfo(notebookName, specialCharacterName)
    String notebookName, specialCharacterName
    String typeStr=SpecialCharacterInfo(notebookName, specialCharacterName, "TYPE")
    String locStr=SpecialCharacterInfo(notebookName, specialCharacterName, "LOC")
    Printf "TYPE: %s\r", typeStr
    Printf "LOC: %s\r", locStr
End
```

**See Also**

The **Notebook** and **NotebookAction** operations; the **SpecialCharacterList** function.

**SpecialCharacterList**

**SpecialCharacterList**(*notebookNameStr*, *separatorStr*, *mask*, *flags*)

The **SpecialCharacterList** function returns a string containing a list of names of special characters in a formatted text notebook.

**Parameters**

*notebookNameStr* is the name of a notebook or "" for the top visible notebook.

*separatorStr* should contain a single character, usually semicolon, to separate the names.

*mask* determines which types of special characters are included. *mask* is a bitwise parameter with values:

- 1: Pictures including graphs, tables and layouts.
- 2: Notebook actions.
- 4: All other special characters such as dates and times.

or a bitwise combination of the above for more than one type. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

*flags* is a bitwise parameter. Pass 0 to include all special characters or 1 to include only selected special characters. All other bits are reserved and should be passed as zero.

**Details**

Only formatted text notebooks have special characters. When called for a plain text notebook, **SpecialCharacterList** always returns "".

**Examples**

Print a list of all special characters in the top notebook:

```
Print SpecialCharacterList("", ";", -1, 0)
```

Prints a list of notebook action characters in Notebook0:

```
Print SpecialCharacterList("Notebook0", ";", 2, 0)
```

Print a list of selected notebook action characters in Notebook0:

```
Print SpecialCharacterList("Notebook0", ";", 2, 1)
```

**See Also**

The **Notebook** and **NotebookAction** operations; the **SpecialCharacterInfo** function.

**SpecialDirPath**

**SpecialDirPath**(*dirIDStr*, *domain*, *flags*, *createdir*)

The **SpecialDirPath** function returns a full path to a file system directory specified by *dirIDStr* and *domain*. It provides a programmer with a way to access directories of special interest, such as the preferences directory and the desktop directory.

The path returned always ends with a separator character which may be a colon, backslash, or forward slash depending on the operating system and the *flags* parameter.

**SpecialDirPath** depends on operating system behavior. The exact path returned depends on the locale, the operating system, the specific installation, the current user, and possibly other factors.

**Parameters**

*dirIDStr* is one of the following strings:

- "Packages" Place for advanced programmers to put preferences for their procedure packages.
- "Documents" The OS-defined place for users to put documents.
- "Preferences" The OS-defined place for applications to put preferences.
- "Desktop" The desktop.
- "Temporary" The OS-defined place for applications to put temporary files.

*domain* permits discriminating between, for example, the preferences folder for all users versus the preferences folder for the current user. It is supported only for certain *dirIDStrs*. It is one of the following:

## sphericalBessJ

---

- 0: The current user (recommended value for most purposes).
- 1: All users (may generate an error or return the same path as 0).
- 2: System (may generate an error or return the same path as 1).

*flags* a bitwise parameter:

Bit 0: If set, the returned path is a native path (Macintosh-style on Mac OS 9, Unix-style on Mac OS X, Windows-style on Windows). If cleared, the returned path is a Macintosh-style path regardless of the current platform. In most cases you should set this bit to zero since Igor accepts Macintosh-style paths on all operating systems. You must set this bit to one if you are going to pass the path to an external script.

All other bits are reserved and must be set to zero.

See **Setting Bit Parameters** on page IV-11 for details about bit settings.

*createDir* is 1 if you want the directory to be created if it does not exist or 0 if you do not want it to be created. This flag will not work if the current user does not have sufficient privileges to create the specified directory. In almost all cases it is not needed, you can't count on it, and you should pass 0.

### Details

The *domain* parameter has no effect in most cases. In almost all cases you should pass 0 (current user) for this parameter. For values other than 0, `SpecialDirPath` might return an error which you must be prepared to handle.

In the event of an error, `SpecialDirPath` returns a NULL string and sets a runtime error code. You can check for an error like this:

```
String fullPath = SpecialDirPath("Packages", 0, 0, 0)
if (!(strlen(fullPath) > 0)) // strlen(NULL) returns NaN
    Print "SpecialDirPath returned error."
endif
```

Here is sample output from the `SpecialDirPath` function on three tested systems.

*dirIDStr* = "Packages", *domain* = 0

**Mac OS 9** hd:System Folder:Preferences:WaveMetrics:Igor Pro 6:Packages:

**Mac OS X** hd:Users:<user>:Library:Preferences:WaveMetrics:Igor Pro 6:Packages:

**Windows 2000** C:Documents and Settings:<user>:Application Data:WaveMetrics:Igor Pro 6:Packages:

where <user> is the name of the current user. The preferences directory may be hidden by some operating systems.

### Example

For an example using `SpecialDirPath`, see **Saving Package Preferences** on page IV-180.

## sphericalBessJ

**sphericalBessJ(*n*, *x* [, *accuracy*])**

The `sphericalBessJ` function returns the spherical Bessel function of the first kind and order *n*.

$$j_n(x) = \sqrt{\frac{\pi}{2x}} J_{n+1/2}(x).$$

For example:

$$j_0(x) = \frac{\sin(x)}{x} \quad j_1(x) = \frac{\sin(x)}{x^2} - \frac{\cos(x)}{x} \quad j_2(x) = \left(\frac{3}{x^3} - \frac{1}{x}\right) \sin(x) - \frac{3}{x^2} \cos(x).$$

### Details

See the `bessI` function for details on accuracy and speed of execution.

### SphericalInterpolate

**SphericalInterpolate** *triangulationDataWave*, *dataPointsWave*, *newLocationsWave*

The SphericalInterpolate operation works in conjunction with the SphericalTriangulate operation to calculate interpolated values on a surface of a sphere. Given a set of  $\{x_i, y_i, z_i\}$  points on the surface of a sphere with their associated values  $\{v_i\}$ , the SphericalTriangulate operation performs the Delaunay triangulation and creates an output that is used by the SphericalInterpolate operation to calculate values at any other point on the surface of a sphere. The interpolation calculation uses Voronoi polygons to weigh the contribution of the nearest neighbors to any given location on the sphere.

#### Parameters

*triangulationDataWave* is a 13 column wave that was created by the SphericalTriangulate operation.

*dataPoints* is a 4 column wave. The first 3 columns are the  $\{x_i, y_i, z_i\}$  locations that were used to create the triangulation, and the last column corresponds to the  $\{v_i\}$  values at the triangulation locations.

*newLocationsWave* is a 3 column wave that specifies the x, y, z locations on the sphere at which the interpolated values are calculated. Note that internally, each triplet is normalized to a point on the unit sphere before it is used in the interpolation.

#### Details

You will always need to use the SphericalTriangulate operation first to generate the *triangulationDataWave* input for this operation.

The result of the operation are put in the wave *W\_SphericalInterpolation*.

#### See Also

The **SphericalTriangulate** operation.

### SphericalTriangulate

**SphericalTriangulate** [/Z] *tripletWaveName*

The SphericalTriangulate operation triangulates an arbitrary XYZ triplet wave on a surface of a sphere.

It starts by normalizing the data to make sure that  $\sqrt{x^2+y^2+z^2}=1$ , and then proceeds to calculate the Delaunay triangulation.

#### Flags

/Z            No error reporting.

#### Details

The result of the triangulation is the wave *M\_SphericalTriangulation*. This 13 column wave is used in SphericalInterpolate to obtain the interpolated values.

#### See Also

The **SphericalInterpolate** operation.

### SplitString

**SplitString** /E=*regExprStr* *str* [, *substring1* [, *substring2*,... *substringN*]]

The SplitString operation uses the regular expression *regExprStr* to split *str* into subpatterns. See **Subpatterns** on page IV-133 for details. Each matched subpattern is returned sequentially in the corresponding substring parameter.

#### Parameters

*str* is the input string to be split into subpatterns.

The *substring1...substringN* output parameters must be the names of existing string variables if you need to use the matched subpatterns. The first matched subpattern is returned in *substring1*, the second in *substring2*, etc.

#### Flags

/E=*regExprStr*        Specifies the Perl-compatible regular expression string containing subpattern definition(s).

#### Details

*regExprStr* is a regular expression with successive subpattern definitions, such as shown in the examples. (Subpatterns are regular expressions within parentheses.)

For unmatched subpatterns, the corresponding substring is set to "". If you specify more substring parameters than subpatterns, the extra parameters are also set to "".

The number of matched subpatterns is returned in `V_flag`.

The part of `str` that matches `regExprStr` (often all of `str`) is stored in `S_value`.

### Examples

```
// Split the output of the date() function:
Print date()
  Mon, May 2, 2005

String expr="([[:alpha:]]+), ([[:alpha:]]+) ([[:digit:]]+), ([[:digit:]]+)"
String dayOfWeek, monthName, dayNumStr, yearStr
SplitString/E=(expr) date(), dayOfWeek, monthName, dayNumStr, yearStr
Print V_flag
  4
Print dayOfWeek
  Mon
Print monthName
  May
Print dayNumStr
  2
Print yearStr
  2005
Print S_value
  Mon, May 2, 2005

// Get the part of str that matches regExprStr
SplitString/E=(",.*,") "stuff in front,second value,stuff at end"
Print S_value
  ,second value,
```

### See Also

The `sscanf` and **Grep** operations. The `strsearch` and `str2num` functions.

## sprintf

**sprintf** *stringName*, *formatStr* [, *parameter*]...

The `sprintf` operation is the same as `printf` except it prints the formatted output to the string variable *stringName* rather than to the history area.

### Parameters

<i>formatStr</i>	See <code>printf</code> .
<i>parameter</i>	See <code>printf</code> .
<i>stringName</i>	Results are "printed" into the named string variable.

### See Also

The `printf` operation for complete format and parameter descriptions and **Creating Formatted Text** on page IV-184.

## sqrt

**sqrt** (*num*)

The `sqrt` function returns the square root of *num* or NaN if *num* is negative. In complex expressions, *num* is complex, and `sqrt(num)` returns a complex value.

## sscanf

**sscanf** *scanStr*, *formatStr*, *var* [, *var*]

The `sscanf` operation is useful for parsing text that contains numeric or string data. It is based on the C `sscanf` function and provides a subset of the features available in C.

Here is a trivial example:

```
Variable v1
sscanf "Value= 1.234", "Value= %f", v1
```

This skips the text "Value=" and the following space and then converts the text "1.234" (or whatever number appeared there) into a number and stores it in the local variable `v1`.

The `sscanf` operation sets the variable `V_flag` to the number of values read. You can use this as an initial check to see if the `scanStr` is consistent with your expectations.

**Note:** The `sscanf` operation is supported in user functions only. It is not available using the command line, using a macro, or using the Execute operation.

### Parameters

`scanStr` contains the text to be parsed.

`formatStr` is a format string which describes how the parsing is to be done.

`formatStr` is followed by the names of one or more local numeric or string variables or NVARs (references to global numeric variables) or SVARs (references to global string variables), which are represented by `var` above.

`sscanf` can handle a maximum of 100 `var` parameters.

### Details

The format string consists of the following:

- Normal text, which is anything other than a percent sign ("%") or white space.
- White space (spaces, tabs, linefeeds, carriage returns).
- A percent ("%") character, which is the start of a conversion specification.

The trivial example illustrates all three of these components.

```
Variable v1
sscanf "Value= 1.234", "Value= %f", v1
```

`sscanf` attempts to match normal text in the format string to the identical normal text in the scan string. In the example, the text "Value=" in the format string skips the identical text in the scan string.

`sscanf` matches a single white space character in the format string to 0 or more white space characters in the scan string. In the example, the single space skips the single space in the scan string.

When `sscanf` encounters a percent character in the format string, it attempts to convert the corresponding text in the scan string into a number or string, depending on the conversion character following the percent, and stores the resulting number or string in the corresponding variable in the parameter list. In the example, "%f" converts the text "1.234" into a number which it stores in the local variable `v1`.

A conversion specification consists of:

- A percent character ("%").
- An optional "\*", which is a conversion suppression character.
- An optional number, which is a maximum field width.
- A conversion character, which specifies how to interpret text in the scan string.

Don't worry about the suppression character and the maximum width specification for now. They will be explained later.

The `sscanf` operation supports a subset of the conversion characters supported by the C `sscanf` operation. The supported conversion characters, which are case-sensitive, are:

- d** Converts text representing a decimal number into an integer numeric value.
- i** Converts text representing a decimal, octal or hexadecimal number into an integer value. If the text starts with "0x" (zero-x), it is interpreted as hexadecimal. Otherwise, if it starts with "0" (zero), it is interpreted as octal. Otherwise it is interpreted as decimal.
- o** Converts text representing an octal number into an integer numeric value.
- u** Converts text representing an unsigned decimal number into an integer numeric value.
- x** Converts text representing a hexadecimal number into an integer numeric value.
- c** Converts a single character into an integer value which is the ASCII code representing that character.
- e** Converts text representing a decimal number into a floating point numeric value.
- f** Same as e.
- g** Same as e.
- s** Stores text up to the next white space into a string.

- [ Stores text that matches a list of specific characters into a string. The list consists of the characters inside the brackets ("%[abc]"). If the first character is "^", this means to match any character that is **not** in the list. You can specify a range of characters to match. For example "%[A-Z]" matches all of the upper case letters and "%[A-Za-z]" matches all of the upper and lower case letters.

Here are some simplified examples to illustrate each of these conversions.

```
Variable v1
String s1
```

Convert text representing a decimal number to an integer value:

```
sscanf "1234", "%d", v1
```

Convert text representing a decimal, octal, or hexadecimal number:

```
sscanf "1.234", "%i", v1           // Convert from decimal.
sscanf "01234", "%i", v1         // Convert from octal.
sscanf "0x123", "%i", v1         // Convert from hex.
```

Convert text representing an octal number:

```
sscanf "1234", "%o", v1
```

Convert text representing an unsigned decimal number:

```
sscanf "1234", "%u", v1
```

Convert text representing a hexadecimal number:

```
sscanf "1FB9", "%x", v1
```

Convert a single character:

```
sscanf "A", "%c", v1
```

Convert text representing a decimal number to an floating point value:

```
sscanf "1.234", "%e", v1
sscanf "1.234", "%f", v1
sscanf "1.234", "%g", v1
```

Copy a string of text up to the first white space:

```
sscanf "Hello There", "%s", s1
```

Copy a string of text matching the specified characters:

```
sscanf "+4.27", "%[+-]", s1
```

In a C program, you will sometimes see the letters "l" (ell) or "h" between the percent and the conversion character. For example, you may see "%lf" or "%hd". These extra letters are not needed or tolerated by Igor's sscanf operation.

When sscanf matches the format string to the scan string, it reads from the scan string until a character that would be inappropriate for the section of the format string that sscanf is trying to match. In the following example, sscanf stops reading characters to be converted into a number when it hits the first character that is not appropriate for a number.

```
Variable v1
String s1, s2
sscanf "1234Volts DC", "%d%s %s", v1, s1, s2
```

sscanf stops matching text for "%d" when it hits "V" and stores the converted number in v1. It stops matching text for the first "%s" when it hits white space and stores the matched text in s1. It then skips the space in the scan string because of the corresponding space in the format string. Finally, it matches the remaining text to the second "%s" and stores the text in s2.

The maximum field width must appear just before the conversion character ("d" in this case).

```
Variable v1, v2
sscanf "12349876", "%4d%4d", v1, v2
```

The suppression character ("\*") is used in a conversion specification to skip values in the scan string. It parses the value, but sscanf does not store the value in any variable. In the following example, we read one number into local variable v1, skip a colon, and read another number into local variable v2, skip a colon, and read another number into local variable v3.

```
Variable v1, v2, v3
sscanf "12:30:45", "%d*[:]d*[:]d", v1, v2, v3
```

Here "%\*[:]" means "read a colon character but don't store it anywhere". The "\*" character must appear immediately after the percent. Note that there is nothing in the parameter list corresponding to the suppressed strings.

## Stack

---

If the text in the scan string is not consistent with the text in the format string, `sscanf` may not read all of the values that you expected. You can check for this using the `V_flag` variable, which is set to the number of values read. This kind of inconsistency does not cause `sscanf` to return an error to Igor, which would cause procedure execution to abort. It is a situation that you can deal with in your procedure code.

The `sscanf` operation returns the following kinds of errors:

- Out-of-memory.
- The number of parameters implied by *formatStr* does not match the number of parameters in the *var* list.
- *formatStr* calls for a numeric variable but the parameter list expects a string variable.
- *formatStr* calls for a string variable but the parameter list expects a numeric variable.
- *formatStr* includes an unsupported, unknown or incorrectly constructed conversion specification.
- The *var* list references a global variable that does not exist.

### Examples

Here is a simple example to give you the general idea:

```
Function SimpleExample()
  Variable v1, valuesRead
  sscanf "Value=1.234", "Value=%g", v1
  valuesRead = V_flag
  if (valuesRead != 1)
    Printf "Error: Expected 1 value, got %d values\r", valuesRead
  else
    Printf "Value read = %g\r", v1
  endif
End
```

For an example that uses `sscanf` to load data from a text file, see the Load File Demo example in "Igor Pro Folder:Examples:Programming".

`str2num`, `strsearch`, and `stringmatch`.

## Stack

**Stack** [*flags*] [*objectName*][, *objectName*]...

The Stack operation stacks the named objects in the top page layout.

### Parameters

*objectName* is the name of a graph, table, picture or annotation object in the top page layout.

### Flags

*/A*=(rows,cols)    */I*    */O*=objTypes    */S*  
*/G*=grout    */M*    */R*    */W*=(left,top,right,bottom)

### See Also

The **Tile** operation for details on the flags and parameters.

## StackWindows

**StackWindows** [*flags*] [*windowName* [, *windowName*]...]

The StackWindows operation stacks the named windows on the desktop.

### Flags

*/A*=(rows,cols)    */G*=grout    */O*=objTypes    */P*    */W*=(left,top,right,bottom)  
*/C*    */I*    */M*    */R*

### See Also

See the **TileWindows** operation for details on the flags and parameters.

## startMSTimer

### startMSTimer

The startMSTimer function creates a new microsecond timer and returns a timer reference number.

### Details

You can create up to ten different microsecond timers using startMSTimer. A valid timer reference number is a number between 0 and 9. If startMSTimer returns -1, there are no free timers available. startMSTimer works in conjunction with stopMSTimer.

### See Also

The stopMSTimer and ticks functions.

## Static

**Static constant** *objectName* = *value*

**Static strconstant** *objectName* = *value*

**Static Function** *funcName*()

**Static Picture** *pictName*

The Static keyword declaration specifies that a constant, user function, or Proc Picture is local to the procedure file in which it appears. Static objects can only be used by other functions; they cannot be accessed from macros; they cannot be accessed from other procedure files or from the command line.

### See Also

Static Functions on page IV-65, Proc Pictures on page IV-44, and Constants on page IV-38.

## StatsAngularDistanceTest

**StatsAngularDistanceTest** [*flags*][*srcWave1*, *srcWave2*, *srcWave3*...]

The StatsAngularDistanceTest operation performs nonparametric tests on the angular distance between sample data and reference directions for two or more samples in individual waves. The angular distance is the shortest distance between two points on a circle (in radians). Specify the sample waves using /WSTR or by listing them following the flags. Set reference directions with /ANG, /ANGW, or the sample mean direction.

### Flags

/ALPH= <i>val</i>	Sets the significance level (default 0.05).
/ANG={ <i>d1</i> , <i>d2</i> }	Sets reference directions (in radians) for two samples; for more than two samples use /ANGW.
/ANGM	Computes the mean direction of each sample and uses it as the reference direction.
/ANGW= <i>dWave</i>	Sets reference directions (in radians) for more than two samples using directions in <i>dWave</i> , which must be single or double precision.
/APRX= <i>m</i>	Controls the approximation method for computing the P-value in the case of two samples (Mann-Whitney Wilcoxon). See <b>StatsWilcoxonRankTest</b> for more details. The default value is 0, which may require long computation times if your sample size is large. Use /APRX=1 if you have a large sample and you expect ties in the data.
/Q	No results printed in the history area.
/T= <i>k</i>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing.
/TAIL= <i>tail</i>	<i>tail</i> =1: Lower tail. <i>tail</i> =2: Upper tail (default). <i>tail</i> =4: Two tail. Use any test combination by adding the values. The P value corresponding to the last tail calculated will be entered in the table.
/WSTR= <i>waveListString</i>	Specifies a string containing a semicolon-separated list of waves that contain sample data. Use <i>waveListString</i> instead of listing each wave after the flags.

## StatsANOVA1Test

---

/Z Ignores errors. V\_flag will be set to -1 for any error and to zero otherwise.

### Details

The inputs for StatsAngularDistanceTest are two or more waves each corresponding to individual sample. The waves must be single or double precision expressing the angles in radians. There is no restriction on the number of points or dimensionality of the waves but the data should not contain NaNs or INFs. We recommend that you use double precision waves, especially if there are ties in the data. The reference directions should also be in radians. For two samples, StatsAngularDistanceTest computes the angular distances between the input data and the reference directions and then uses the Mann-Whitney-Wilcoxon test (**StatsWilcoxonRankTest**). Results are stored in the W\_WilcoxonTest wave and in the corresponding table. For more than two samples, StatsAngularDistanceTest uses the Kruskal-Wallis test, storing results in the wave W\_KWTestResults wave in the current data folder.

V\_flag will be set to -1 for any error and to zero otherwise.

### References

See, in particular, Chapter 27 of:

Zar, J.H., *Biostatistical Analysis*, 4th ed., 929 pp., Prentice Hall, Englewood Cliffs, New Jersey, 1999.

### See Also

Examples:Statistics:Circular Statistics:AngularDistanceTest.pxp.

## StatsANOVA1Test

**StatsANOVA1Test** [ *flags* ] [ *wave1, wave2, ... wave100* ]

The StatsANOVA1Test operation performs a one-way ANOVA test (fixed-effect model). The standard ANOVA test results are stored in the M\_ANOVA1 wave in the current data folder.

### Flags

/ALPH=*val* Sets the significance level (default 0.05).  
/BF Performs the Brown and Forsythe test computing F' and degrees of freedom. The W\_ANOVA1BnF wave in the current data folder contains the output.  
/Q No results printed in the history area.  
/T=*k* Displays results in a table; additional tables are created with /BF and /W. *k* specifies the table behavior when it is closed.  
*k*=0: Normal with dialog (default).  
*k*=1: Kills with no dialog.  
*k*=2: Disables killing.  
/W Performs the Welch test F' and computes degrees of freedom. The W\_ANOVA1Welch wave in the current data folder contains the output.  
/WSTR=*waveListString* Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.  
/Z Ignores errors. V\_flag will be set to -1 for any error and to zero otherwise.

### Details

Inputs to StatsANOVA1Test are two or more 1D numerical waves containing (one wave for each group of samples). Use NaN for missing entries or use waves with different numbers of points. The standard ANOVA results are in the M\_ANOVA1 wave with corresponding row and column labels. Use /T to display the results in a table. In each case you will get the two degrees of freedom values, the F value, the critical value Fc for the choice of alpha and the degrees of freedom, and the P-value for the result. V\_flag will be set to -1 for any error and to zero otherwise.

In some cases the ANOVA test may not be appropriate. For example, if groups do not exhibit sufficient homogeneity of variances. Although this may not be fatal for the ANOVA test, you may get more insight by performing the variances test in **StatsVariancesTest**.

If there are only two groups this test should be equivalent to **StatsTTest**.

You can evaluate the power of an ANOVA test for a given set of degrees of freedom and noncentrality parameter using:

```
power=1-StatsNCFCDF(StatsInvFCDF((1-alpha),n1,n2),n1,n2,delta)
```

Here  $n_1$  is the Groups' degrees of freedom,  $n_2$  is the Error degrees of freedom, and  $\delta$  is the noncentrality parameter. For more information see ANOVA Power Calculations Panel and the associated example experiment.

Chapter III-12, **Statistics** for a function and operation overview; **StatsVariancesTest**, **StatsTTest**, **StatsNCFCDF**, and **StatsInvFCDF**.

## StatsANOVA2NRTest

### StatsANOVA2NRTest [flags] srcWave

The StatsANOVA2NRTest operation performs a two-factor analysis of variance (ANOVA) on the data that has no replication where there is only a single datum for every factor level. *srcWave* is a 2D wave of any numeric type. Output is to the M\_ANOVA2NRResults wave in the current data folder or optionally to a table.

### Flags

/ALPH=*val* Sets the significance level (default 0.05).  
 /FOMD Estimates one missing value. You will also have to use a single or double precision wave for *srcWave* and designate the single missing value as NaN. The estimated value is printed to the history as well as the bias used to correct the sum of the squares of factor A.  
 /INT=*val* Sets the degree of interactivity.  
*val*=0: No interaction between the factors (default).  
*val*=1: Significant interaction effect between factors.  
 Combination with /MODL determines which factors to test:

<i>val</i>	Model 1	Model2	Model3
1		A&B	A
0	A&B	A&B	A&B

/MODL=*m* Sets the model number.  
*m*=1: Factor A and factor B are fixed.  
*m*=2: Both factors are random.  
*m*=3: Factor A is fixed and factor B is random (default).  
 /Q No results printed in the history area.  
 /T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.  
*k*=0: Normal with dialog (default).  
*k*=1: Kills with no dialog.  
*k*=2: Disables killing.  
 The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.  
 /Z Ignores errors. V\_flag will be set to -1 for any error and to zero otherwise.

### Details

Input to StatsANOVA2NRTest is the 2D *srcWave* in which the factor A levels are columns and the factor B levels are rows. NaN and INF entries are not supported although you may use a single NaN value in combination with the /FOMD. If *srcWave* contains dimension labels they will be used to designate the two factors in the output.

The contents of the M\_ANOVA2NRResults output wave columns are: the first contains the sum of the squares (SS) values, the second contains the degrees of freedom (DF), the third contains the mean square (MS) values, the fourth contains the computed F value for this test, the fifth contains the critical F value ( $F_c$ )

## StatsANOVA2RMTTest

---

for the specified alpha, and the last contains the conclusion with 0 to reject  $H_0$  or 1 to accept it. In each case  $H_0$  corresponds to the assumption that there is no difference in the means of the respective populations.

V\_flag will be set to -1 for any error and to zero otherwise.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsANOVA1Test** and **StatsANOVA2Test**.

## StatsANOVA2RMTTest

### **StatsANOVA2RMTTest** [ *flags* ] *srcWave*

The StatsANOVA2RMTTest operation performs analysis of variance (ANOVA) on *srcWave* where replicates consist of multiple measurements on the same subject (repeated measures). *srcWave* is a 2D wave of any numeric type. Output is to the M\_ANOVA2RMResults wave in the current data folder or optionally to a table.

### Flags

/ALPH= <i>val</i>	Sets the significance level (default 0.05).
/Q	No results printed in the history area.
/T= <i>k</i>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing. The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
/Z	Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

### Details

Input to StatsANOVA2RMTTest is the 2D *srcWave* in which the factor A (Groups) are columns and the different subjects are rows. It does not support NaNs or INFs.

The contents of the M\_ANOVA2RMResults output wave columns are: the first contains the sum of the squares (SS) values, the second contains the degrees of freedom (DF), the third contains the mean square (MS) values, the fourth contains the single F value for this test, the fifth contains the critical F value for the specified alpha and degrees of freedom, and the last column contains the conclusion with 0 to reject  $H_0$  or 1 to accept it. In each case  $H_0$  corresponds to the mean level, which is the same for all subjects.

V\_flag will be set to -1 for any error and to zero otherwise.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsANOVA2NRTest** and **StatsANOVA2Test**.

## StatsANOVA2Test

### **StatsANOVA2Test** [ *flags* ] *srcWave*

The StatsANOVA2Test operation performs a two-factor analysis of variance (ANOVA) on *srcWave*. Output is to the M\_ANOVA2Results wave in the current data folder or optionally to a table.

### Flags

/ALPH= <i>val</i>	Sets the significance level (default 0.05).
/FAKE= <i>num</i>	Specifies the number of points in <i>srcWave</i> obtained by "estimation". <i>num</i> is subtracted from the total and error degrees of freedom.
/MODL= <i>m</i>	Sets the model number. <i>m</i> =1: Factor A and factor B are fixed (default). <i>m</i> =2: Both factors are random. <i>m</i> =3: Factor A is fixed and factor B is random.
/Q	No results printed in the history area.
/T= <i>k</i>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default).

$k=1$ : Kills with no dialog.

$k=2$ : Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

/Z

Ignores errors. V\_flag will be set to -1 for any error and to zero otherwise.

### Details

Input to StatsANOVA2Test is the single or double precision 3D *srcWave* in which the factor A levels are columns, the factor B levels are rows, and the replicates are layers. If *srcWave* contains dimension labels they will be used to designate the factors in the output.

Ideally, the number of replicates must be equal for each factor and each level. StatsANOVA2Test supports both equal replication and proportional replication. Proportional replication allows for different number of data in each cell with missing data represented as NaN and the number of points in each cell is given by

$N_{ij} = (\text{sum of data in row } i) * (\text{sum of data in column } j) / \text{number of samples}$ .

If you have no replicates (a single datum per cell) use **StatsANOVA2NRTest** instead. If the number of replicates in your data does not satisfy these conditions you may be able to “estimate” additional replicates using various methods. In that case use the /FAKE flag so that the operation can account for the estimated data by reducing the total and error degrees of freedom. /FAKE only accounts for the number of estimates being used. You must provide an appropriate number of estimated values.

The contents of the M\_ANOVA2Results output wave columns are: the first contains the sum of the squares (SS) values, the second the degrees of freedom (DF), the third contains the mean square (MS) values, the fourth contains the computed F value for this test, the fifth contains the critical Fc value for the specified alpha and degrees of freedom, and the last contains the conclusion with 0 to reject  $H_0$  or 1 to accept it. In each case  $H_0$  corresponds to the mean level, which is the same for all populations.

V\_flag will be set to -1 for any error and to zero otherwise.

## StatsBetaCDF

**StatsBetaCDF(x, p, q [, a, b])**

The StatsBetaCDF function returns the beta cumulative distribution function

$$F(x;p,q,a,b) = \frac{1}{B(p,q)} \int_0^x t^{p-1} (1-t)^{q-1} dt, \quad \begin{array}{l} p,q > 0 \\ a \leq x \leq b \end{array}$$

where  $B(p,q)$  is the beta function  $B(p,q) = \int_0^1 t^{p-1} (1-t)^{q-1} dt$ .

The defaults ( $a=0$  and  $b=1$ ) correspond to the standard beta distribution where  $a$  is the location parameter, ( $b-a$ ) is the scale parameter, and  $p$  and  $q$  are shape parameters.

## StatsBetaPDF

**StatsBetaPDF(x, p, q [, a, b])**

The StatsBetaPDF function returns the beta probability distribution function

$$f(x;p,q,a,b) = \frac{(x-a)^{p-1} (b-x)^{q-1}}{B(p,q)(b-a)^{p+q-1}}, \quad \begin{array}{l} a \leq x \leq b \\ p,q > 0 \end{array}$$

where  $B(p,q)$  is the beta function  $B(p,q) = \int_0^1 t^{p-1} (1-t)^{q-1} dt$ .

## StatsBinomialCDF

---

The defaults ( $a=0$  and  $b=1$ ) correspond to the standard beta distribution where  $a$  is the location parameter, ( $b-a$ ) is the scale parameter, and  $p$  and  $q$  are shape parameters. When  $p < 1$ ,  $f(x=a)$  returns Inf.

Chapter III-12, **Statistics** for a function and operation overview; **StatsCauchyCDF** and **StatsInvCauchyCDF**.

## StatsChiCDF

### StatsChiCDF(*x*, *n*)

The StatsChiCDF function returns the chi-squared cumulative distribution function for the specified value and degrees of freedom *n*.

$$F(x,n) = \frac{\gamma\left(\frac{n}{2}, \frac{x}{2}\right)}{\Gamma\left(\frac{n}{2}\right)}$$

where  $\gamma(a,b)$  is the incomplete gamma function. The distribution can also be expressed as

$$F(x,n) = 1 - \text{gammapq}\left(\frac{n}{2}, \frac{x}{2}\right)$$

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsChiPDF**, **StatsInvChiCDF**, and **gammapq**.

## StatsChiPDF

### StatsChiPDF(*x*, *n*)

The StatsChiPDF function returns the chi-squared probability distribution function for the specified value and degrees of freedom as

$$f(x,n) = \frac{\exp\left(-\frac{x}{2}\right) x^{\frac{n}{2}-1}}{2^{\frac{n}{2}} \Gamma\left(\frac{n}{2}\right)}$$

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsChiCDF** and **StatsChiPDF**.

## StatsChiTest

### StatsChiTest [*flags*] *srcWave1*, *srcWave2*

The StatsANOVA2Test operation computes a  $\chi^2$  statistic for comparing two distributions or a  $\chi^2$  statistic for comparing a sample distribution with its expected values. In both cases the comparison is made on a bin-by-bin basis. Output is to the W\_StatsChiTest wave in the current data folder or optionally to a table.

### Flags

- /NCON*=*nCon*      Specifies the number of constraints (0 by default), which reduces the number degrees of freedom and the critical value by *nCon*.
- /S*                      Sets the calculation mode to a single distribution where *srcWave1* represents an array of binned measurements and *srcWave2* represents the corresponding expected values.
- /T*=*k*                    Displays results in a table. *k* specifies the table behavior when it is closed.
  - k*=0:      Normal with dialog (default).
  - k*=1:      Kills with no dialog.
  - k*=2:      Disables killing.
- /Z*                      Ignores errors. V\_wave will be set to -1 for any error and to zero otherwise.

### Details

The source waves, *srcWave1* and *srcWave2*, must have the same number of points and can be any real numeric data type. Any nonpositive values (including NaN) in either wave removes the entry in both waves from consideration and reduces the degrees of freedom by one. The number degrees of freedom is initially the number of points in *srcWave1*-1-*nCon*. By default it is assumed that *srcWave1* and *srcWave2* represent two distributions of binned data.

When you specify */S*, *srcWave1* must consist of binned values of measured data and *srcWave2* must contain the corresponding expected values. The calculation is:

## StatsCircularCorrelationTest

---

$$\chi^2 = \sum_{i=0}^{n-1} \frac{(Y_i - V_i)^2}{V_i}$$

Here  $Y_i$  is the sample point from *srcWave1*,  $V_i$  is the expected value of  $Y_i$  based on an assumed distribution (*srcWave2*), and  $n$  is the number of points in the each wave. If you do not use /S, it calculates:

$$\chi^2 = \sum_{i=0}^{n-1} \frac{(Y_{1i} - Y_{2i})^2}{Y_{1i} + Y_{2i}}$$

where  $Y_{1i}$  and  $Y_{2i}$  are taken from *srcWave1* and *srcWave2* respectively.

V\_flag will be set to -1 for any error and to zero otherwise.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsContingencyTable**.

## StatsCircularCorrelationTest

### StatsCircularCorrelationTest [ flags ] waveA, waveB

The StatsCircularTwoSampleTest operation performs parametric and nonparametric tests for angular-angular and angular-linear correlations. Input waves, *waveA* and *waveB*, contain angles (in radians) as either single or double precision values and must have the same number of points. If you make more than one test, they are in the order /PAA, /PAL, and /NAA. Output is to the W\_StatsCircularCorrelationTest wave in the current data folder or optionally to a table.

### Flags

/ALPH=val	Sets the significance level (default 0.05).
/NAA	Performs a nonparametric angular-angular correlation test.
/PAA	Performs a parametric angular-angular correlation test.
/PAL	Performs a parametric angular-linear correlation test. In this case the angle wave is <i>waveA</i> and the linear data corresponds to <i>waveB</i> .
/Q	No results printed in the history area.
/T=k	Displays results in a table. $k$ specifies the table behavior when it is closed. $k=0$ : Normal with dialog (default). $k=1$ : Kills with no dialog. $k=2$ : Disables killing.
/Z	Ignores errors.

### Details

The nonparametric test (/NAA) follows Fisher and Lee's modification of Mardia's statistic, which is an analogue of Spearman's rank correlation. The test ranks the angles of each sample and computes the quantities  $r'$  and  $r''$  as follows:

$$r' = \frac{\left\{ \sum_{i=0}^{n-1} \cos \left[ \frac{2\pi}{n} (r_{ai} - r_{bi}) \right] \right\}^2 + \left\{ \sum_{i=0}^{n-1} \sin \left[ \frac{2\pi}{n} (r_{ai} - r_{bi}) \right] \right\}^2}{n^2}$$
$$r'' = \frac{\left\{ \sum_{i=0}^{n-1} \cos \left[ \frac{2\pi}{n} (r_{ai} + r_{bi}) \right] \right\}^2 + \left\{ \sum_{i=0}^{n-1} \sin \left[ \frac{2\pi}{n} (r_{ai} + r_{bi}) \right] \right\}^2}{n^2}$$

Here  $n$  is the number of data pairs and  $r_{ai}$  and  $r_{bi}$  are the ranks of the  $i$ th member in the first and second samples respectively.

The test statistic is  $(n-1)(r'-r'')$ , which is compared with the critical value (for one and two tails). The CDF of the statistic is a highly irregular function. The critical value is computed by a different methods according to  $n$ . For  $3 \leq n \leq 8$ , a built-in table of CDF transitions gives a "conservative" estimate of the critical value. For

$9 \leq n \leq 30$ , the CDF is approximated by a 7th order polynomial in the region  $x > 0$ . For  $n \geq 30$ , the CDF is from the asymptotic expression. For  $3 \leq n \leq 30$ , CDF values are obtained by Monte-Carlo simulations using  $1e6$  random samples for each  $n$ .

The parametric test for angular-angular correlation (/PAA) involves computation of a correlation coefficient  $r_{aa}$  and then evaluating the mean  $\overline{r_{aa}}$  and variance  $s_{r_{aa}}^2$  of equivalent correlation coefficients computed from the same data but by deleting a different pair of angles each time. The mean and variance are then used to compute confidence limits L1 and L2:

$$L1 = n\overline{r_{aa}} - (n-1)\overline{r_{aa}} - Z_{\alpha(2)}\sqrt{\frac{s_{r_{aa}}^2}{n}} \quad L2 = n\overline{r_{aa}} - (n-1)\overline{r_{aa}} + Z_{\alpha(2)}\sqrt{\frac{s_{r_{aa}}^2}{n}}$$

where  $Z_{\alpha(2)}$  is the normal distribution two-tail critical value at the a level of significance.  $H_0$  (corresponding to no correlation) is rejected if zero is not contained in the interval [L1,L2].

The parametric test for angular-linear correlation (/PAL) involves computation of the correlation coefficient  $r_{al}$  which is then compared with a critical value from  $\chi^2$  for alpha significance and two degrees of freedom.

$$r_{al} = \sqrt{\frac{r_{ac}^2 + r_{bc}^2 - 2r_{ac}r_{bc}r_{cc}}{1 - r_{cc}^2}}$$

where:

$$r_{ac} = \frac{\sum_{i=0}^{n-1} X_i \cos(a_i) - \frac{1}{n} \sum_{i=0}^{n-1} X_i \sum_{i=0}^{n-1} \cos(a_i)}{\sqrt{\left(\sum_{i=0}^{n-1} X_i^2 - \frac{1}{n} \left(\sum_{i=0}^{n-1} X_i\right)^2\right) \left(\sum_{i=0}^{n-1} \cos^2(a_i) - \frac{1}{n} \left(\sum_{i=0}^{n-1} \cos(a_i)\right)^2\right)}}$$

$$r_{bc} = \frac{\sum_{i=0}^{n-1} X_i \sin(a_i) - \frac{1}{n} \sum_{i=0}^{n-1} X_i \sum_{i=0}^{n-1} \sin(a_i)}{\sqrt{\left(\sum_{i=0}^{n-1} X_i^2 - \frac{1}{n} \left(\sum_{i=0}^{n-1} X_i\right)^2\right) \left(\sum_{i=0}^{n-1} \sin^2(a_i) - \frac{1}{n} \left(\sum_{i=0}^{n-1} \sin(a_i)\right)^2\right)}}$$

$$r_{cc} = \frac{\sum_{i=0}^{n-1} \cos(a_i) \sin(a_i) - \frac{1}{n} \sum_{i=0}^{n-1} \sin(a_i) \sum_{i=0}^{n-1} \cos(a_i)}{\sqrt{\left(\sum_{i=0}^{n-1} \sin^2(a_i) - \frac{1}{n} \left(\sum_{i=0}^{n-1} \sin(a_i)\right)^2\right) \left(\sum_{i=0}^{n-1} \cos^2(a_i) - \frac{1}{n} \left(\sum_{i=0}^{n-1} \cos(a_i)\right)^2\right)}}$$

Chapter III-12, **Statistics** for a function and operation overview; **StatsInvChiCDF**, **StatsInvNormalCDF**, and **StatsKendallTauTest**.

## StatsCircularMeans

### StatsCircularMeans [ flags ] srcWave

The StatsCircularMeans operation calculates the mean of a number of circular means, returning the mean angle (grand mean), the length of the mean vector, and optionally confidence interval around the mean angle. Output is to the history area and to the W\_CircularMeans wave in the current data folder.

### Flags

/ALPH=val      Sets the significance level (default 0.05).  
 /CI              Calculates the confidence interval (labeled CI\_t1 and CI\_t2) around the mean angle.  
 /NSOA          Performs nonparametric second order analysis according to Moore's version of Rayleigh's test where  $H_0$  corresponds to uniform distribution around the circle. Moore's test ranks entries by the lengths of the mean radii (second column of the input) from smallest (rank 1) to largest (rank  $n$ ) and then computes the statistic:

$$R^* = \sqrt{\frac{\left(\frac{1}{n} \sum_{i=0}^{n-1} (i+1) \cos(a_i)\right)^2 + \left(\frac{1}{n} \sum_{i=0}^{n-1} (i+1) \sin(a_i)\right)^2}{n}}$$

where  $a_i$  are the mean angle entries (from column 1) corresponding to vector length rank  $(i+1)$ . The critical value is obtained from Moore's distribution **StatsInvMooreCDF**.

/PSOA

Perform parametric second order analysis where  $H_0$  corresponds to no mean population direction. It assumes that the second order quantities are from a bivariate normal distribution. If this is not the case, use /NSOA above. The test statistic is:

$$F = \frac{k(k-2)2 \left[ \bar{X}^2 S_{y^2} - 2\bar{X}\bar{Y}S_{xy} + \bar{Y}^2 S_{x^2} \right]}{2 \left[ \frac{S_{x^2} S_{y^2} - S_{xy}^2}{n} \right]}$$

where

$$\begin{aligned} \bar{X} &= \frac{1}{n} \sum_{i=0}^{n-1} X_i = \frac{1}{n} \sum_{i=0}^{n-1} r_i \cos(a_i) & \bar{Y} &= \frac{1}{n} \sum_{i=0}^{n-1} Y_i = \frac{1}{n} \sum_{i=0}^{n-1} r_i \sin(a_i) & S_{x^2} &= \sum_{i=0}^{n-1} X_i^2 - \frac{1}{n} \left( \sum_{i=0}^{n-1} X_i \right)^2 \\ S_{y^2} &= \sum_{i=0}^{n-1} Y_i^2 - \frac{1}{n} \left( \sum_{i=0}^{n-1} Y_i \right)^2 & S_{xy} &= \sum_{i=0}^{n-1} X_i Y_i - \frac{1}{n} \sum_{i=0}^{n-1} X_i \sum_{i=0}^{n-1} Y_i \end{aligned}$$

Here  $n$  is the number of means in *srcWave* and the critical value is computed from the F distribution, equivalent to executing: `Print StatsInvFCDF(1-alpha, 2, n-2)`.

/Q

No results printed in the history area.

/T=k

Displays results in a table.  $k$  specifies the table behavior when it is closed.

$k=0$ : Normal with dialog (default).

$k=1$ : Kills with no dialog.

$k=2$ : Disables killing.

/Z

Ignores errors. `V_flag` will be set to -1 for any error and to zero otherwise.

**Details**

The *srcWave* input to **StatsCircularMeans** must be a single or double precision two column wave containing in each row a mean angle (radians) and the length of a mean radius (the first column contains mean angles and the second column contains mean vector lengths). *srcWave* must not contain any NaNs or INFs. The confidence interval calculation follows the procedure outlined by Batschelet.

`V_flag` will be set to -1 for any error and to zero otherwise.

**References**

Zar, J.H., *Biostatistical Analysis*, 4th ed., 929 pp., Prentice Hall, Englewood Cliffs, New Jersey, 1999.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsCircularMoments**, **StatsInvMooreCDF**, and **StatsInvFCDF**.

**StatsCircularMoments**

**StatsCircularMoments** [*flags*] *srcWave*

The **StatsCircularMoments** operation computes circular statistical moments and optionally performs angular uniformity tests for the data in *srcWave*. The extent of the calculation is determined by the requested moment. The default results are stored in the `W_CircularStats` wave in the current data folder and are optionally displayed in a table. Additional results are listed under the corresponding flags.

**Flags**

/ALPH=*alpha*

Sets an *alpha* value for computing confidence intervals (default is 0.05).

/AXD=*p*

Designates the input as *p*-axial data. For example, if the input represents undirected lines then  $p=2$  and the operation multiplies the angles by a factor  $p$  (after shifting /ORGN and accounting for /CYCL). It does not back-transform the mean or median axis.

- /CYCL=cycle* Specifies the length of the data cycle. You do not need to do so if you are using one of the built-in modes, but this is still a useful option, as for setting the length of a particular month when using */MODE=5*.
- /GRPD={start, delta}* Computes circular statistics for grouped data. In this case *srcWave* contains frequencies or the number of events that belong to a particular angle group. There are as many groups as there are elements in *srcWave*. The first group is centered at *start* radians and each consecutive group is centered *delta* radians away. You must set both the *start* and *delta* to sensible values. *srcWave* may contain NaNs but it is an error if all values are NaN. The only other flags that work in combination with this flag are */Q*, */T*, and */Z*.
- /KUPR* Tests the uniformity of the distribution for ungrouped data using Kuiper statistic. The data are converted into a set  $\{x_i\}$  by normalizing the input angles to the range  $[0,1]$ , ranking the results then using the two quantities  $D_+$  and  $D_-$  to compute the Kuiper statistic
 
$$V = (D_+ + D_-)(\sqrt{n} + 0.155 + 0.24/\sqrt{n})$$
 where
 
$$D_+ = \text{Max of: } \frac{1}{n} - x_0, \frac{2}{n} - x_1, \dots, 1 - x_{n-1} \quad D_- = \text{Max of: } x_0, x_1 - \frac{1}{n}, \dots, x_{n-1} - \frac{n-1}{n}$$
 and  $n$  is the number of valid points in *srcWave*. You can find the results in the wave *W\_CircularStats* under row label "Kuiper V" and "Kuiper CDF(V)". See Fisher and Press *et al.* for more information.
- /LOS* Computes Linear Order Statistics by sorting the angle values from small to large, dividing each angle by  $2\pi$  and shifting the origin so that the output range is  $[0,1]$ . The results are stored in the wave *W\_LinearOrderStats* in the current data folder. The X scaling of the wave is set so that the offset and the delta are  $1/(n+1)$  where  $n$  is the number of non-NaN points in the input.
- /M=moment* Computes specified moments. By default, it computes the second order moments as well as skewness, kurtosis, median, and mean deviation. Use */M=1* for the first moment. For higher moments, both the specified moment and all the default quantities are computed.
- /MODE=mode* Handles special types of data.

<i>mode</i>	Data in <i>srcWave</i>
0	Angles in radians $[0, 2\pi]$
1	Angles in radians $[-\pi, \pi]$
2	Angles in degrees $[0, 360]$
3	Angles in degrees $[-180, 180]$
4	Igor date format for one year cycles.
5	Igor date format for one month cycles.
6	Igor date format for one week cycles.
7	Igor date format for one day cycles.
8	Igor date format for one hour cycles.

- /ORGN=origin* Specifies the origin of the data (the value corresponding to an angle of zero degrees). For example, if you are using Igor date format and you want the origin to be the first second in year YYYY, use */ORGN=(date2secs(YYYY, 1, 1))*.
- /Q* No results printed in the history area.
- /RAYL[=meanDirection]* Performs the Rayleigh test for uniformity. If the "alternative" mean direction is specified (in radians), the test computes  $r0Bar = rBar \cos(tBar - meanDirection)$  and then computes the significance probability of  $r0Bar$ . The null hypothesis  $H_0$  corresponds to uniformity. It is rejected when  $r0Bar$  is too large. If the mean direction is not specified then  $r0Bar$  is  $rBar$  which is always calculated as part of the first moments so

the operation only computes the relevant significance probability (P-Value). The critical values for both cases are computed according to Durand and Greenwood.

/SAW Saves the translated angle data in the wave W\_AngleWave in the current data folder.

/T=k Displays results in a table. k specifies the table behavior when it is closed.

k=0: Normal with dialog (default).

k=1: Kills with no dialog.

k=2: Disables killing.

The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results unless you moved the output wave to a different data folder. If the named table exists, but does not display the output wave from the current data folder, the table is renamed and a new table is created.

/Z Ignores errors. V\_flag will be set to -1 for any error and to zero otherwise.

**Details**

StatsCircularMoments is equivalent to **WaveStats** but it applies to circular data, which are distributed on the perimeter of a circle representing some period or cycle. If your data are not described by one of the built-in modes, you can specify the value of the origin (/ORGN), which is mapped to zero degrees and the size of a cycle or period.

When you use Igor date formats with the built-in modes for dates, the default origin is set to zero. The default cycle in the case of Mode 4 is 366. This is done in order to handle both leap and nonleap years. Similarly, Mode 5 uses a cycle of 31 days. Note that the internal conversion from Igor date to (year, month, day) is independent of the cycle specification and is therefore not affected by this choice. You should use the /CYCL flag if you use one of these modes with a fixed size of year or month.

The parameters listed below are computed and displayed (see row labels) in the table. Here N is the number of valid (non-NaN) angles {θ<sub>i</sub>}

$$C = \sum_{i=1}^n \cos\theta_i \quad S = \sum_{i=1}^n \sin\theta_i \quad R = \sqrt{C^2 + S^2}$$

$$cBar = \bar{C} = C/n \quad sBar = \bar{S} = S/n \quad rBar = \bar{R} = R/n \quad tBar = \bar{\theta} = \begin{cases} \text{atan}(S/C) & S > 0, C > 0 \\ \text{atan}(S/C) + \pi & C > 0 \\ \text{atan}(S/C) + 2\pi & S < 0, C > 0 \end{cases}$$

$$V = 1 - \bar{R} \quad v = \sqrt{-2\log(1 - V)}$$

median is the value which minimizes  $d(\theta) = \pi - \frac{1}{n} \sum_{i=1}^n |\pi - |\theta_i - \bar{\theta}||$

mean deviation = The minimum of the last equation when q → median.

Higher order moments are denoted with the moment number such that t3Bar is the uncentered third moment of the angle while primed quantities are relative to mean direction tBar. Using this notation

$$\hat{\rho}_2 = \frac{1}{n} \sum_{i=1}^n \cos 2(\theta_i - \bar{\theta})$$

$$\text{circular dispersion} = \frac{1 - \hat{\rho}_2}{2\bar{R}^2} \quad \text{skewness} = \frac{\hat{\rho}_2 \sin(\hat{\mu}'_2 - 2\bar{\theta})}{(1 - \bar{R})^{3/2}} \quad \text{kurtosis} = \frac{\hat{\rho}_2 \cos(\hat{\mu}'_2 - 2\bar{\theta}) - \bar{R}^4}{(1 - \bar{R})^2}$$

$$\text{where } \hat{\mu}'_p = \begin{cases} \text{atan}(S_p/C_p) & S_p > 0, C_p > 0 \\ \text{atan}(S_p/C_p) + \pi & C_p < 0 \\ \text{atan}(S_p/C_p) + 2\pi & S_p < 0, C_p > 0 \end{cases} \quad \text{and } C_p = \frac{1}{n} \sum_{i=1}^n \cos p\theta_i \quad S_p = \frac{1}{n} \sum_{i=1}^n \sin p\theta_i.$$

## StatsCircularTwoSampleTest

**StatsCircularTwoSampleTest** [*flags*] *waveA*, *waveB*

The StatsCircularTwoSampleTest operation performs second order analysis of angles. Using the appropriate flags you can choose between parametric or nonparametric, unordered or paired tests. The input consists of two waves that contain one or two columns. The first column contains angle data (mean angles) expressed in radians and an optional second column that contains associated vector lengths. The waves must be either single or double precision. Results are stored in the W\_StatsCircularTwoSamples wave in the current data folder and optionally displayed in a table. Some of the tests may have additional outputs.

#### Flags

/ALPH = <i>val</i>	Sets the significance level (default <i>val</i> =0.05).
/NPR	Performs nonparametric paired-sample test (Moore). The input waves must contain paired angular data so both must have single column and the same number of points.
/NSOA	Perform nonparametric second order two-sample test. Input waves must each contain two columns.
/PPR	Performs parametric paired-sample test. Input waves must contain paired data and must have the same number of points.
/PSOA	Performs parametric second order analysis of two samples. The input waves must each contain two columns.
/Q	No information printed in the history area.
/T= <i>k</i>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing.
/Z	Ignores any errors.

#### Details

The nonparametric paired-sample test (/NPR) is Moore's test for paired angles applied in second order analysis. The input can consist of one or two column waves. When both waves contain a single column the operation proceeds as if all the vector length were identically 1. The Moore statistic ( $H_0 \rightarrow$  pair equality) is computed and compared to the critical value from the Moore distribution (see **StatsInvMooreCDF**).

The nonparametric second-order two-sample test (/NSOA) consists of pre-processing where the grand mean is subtracted from the two inputs followed by application of Watson's  $U^2$  test (**StatsWatsonUSquaredTest**) with  $H_0$  implying that the two samples came from the same population. The results of this test are stored in the wave W\_WatsonUtest.

The parametric paired-sample test (/PPR) is due to Hotelling. In this test the input should consist of both angular and vector length data. The test statistic is compared with a critical value from the F distribution (**StatsInvFCDF**).

The parametric second order two-sample test (/PSOA) is an extension of Hotelling one-sample test to second order analysis where an F-like statistic is computed corresponding to  $H_0$  of equal mean angles.

Chapter III-12, **Statistics** for a function and operation overview; **StatsInvMooreCDF**, **StatsWatsonUSquaredTest**, and **StatsInvFCDF**.

**StatsCMSSDCDF****StatsCMSSDCDF** (*C*, *n*)

The StatsCMSSDCDF function returns the cumulative distribution function of the C distribution (mean square successive difference), which is

$$f(C, n) = \frac{\Gamma(2m+2)}{a2^{2m+1}[\Gamma(m+1)]^2} \left(1 - \frac{C^2}{a^2}\right)^m \quad \text{where } a^2 = \frac{(n^2 + 2n - 12)(n - 2)}{(n^2 - 13n + 24)} \quad m = \frac{(n^2 - n^2 - 13n^2 + 37n - 60)}{2(n^2 - 13n + 24)}$$

The distribution ( $C > 0$ ) can then be expressed as

$$F(C, n) = \frac{\Gamma(2m+2)}{a2^{2m+1}[\Gamma(m+1)]^2} C {}_2F_1\left(\frac{1}{2}, -m, \frac{3}{2}, \frac{C^2}{a^2}\right) \quad \text{where } {}_2F_1 \text{ is the hypergeometric function } \mathbf{hyperG2F1}.$$

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsCMSSDCDF** and **StatsSRTest**.

**StatsCochranTest****StatsCochranTest** [*flags*] [*wave1*, *wave2*, ... *wave100*]

The StatsCochranTest operation performs Cochran's (Q) test on a randomized block or repeated measures dichotomous data. Output is to the M\_CochranTestResults wave in the current data folder or optionally to a table.

**Flags**

/ALPH = *val*      Sets the significance level (default *val*=0.05).  
 /Q                    No results printed in the history area.  
 /T=*k*                Displays results in a table. *k* specifies the table behavior when it is closed.  
                       *k*=0:    Normal with dialog (default).  
                       *k*=1:    Kills with no dialog.  
                       *k*=2:    Disables killing.

The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results unless you moved the output wave to a different data folder. If the named table exists but it does not display the output wave from the current data folder, the table is renamed and a new table is created.

/WSTR=*waveListString*  
                       Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.  
 /Z                    Ignores errors. V\_flag will be set to -1 for any error and to zero otherwise.

**Details**

The StatsCochranTest computes Cochran's statistic and compares it to a critical value from a Chi-squared distribution, which depends only of the significance level and the number of groups (columns). The Chi-square distribution is appropriate when there are at least 4 columns and at least 24 total data.

Dichotomous data are presumed to consist of two values 0 and 1, thus StatsCochranTest distinguishes only between zero and any nonzero value, which is considered to be 1; it does not allow NaNs or INFs. Input waves can be a single 2D wave or a list of 1D numeric waves, which can also be specified in a string list with /WSTR. In the standard terminology, data rows represent blocks and data columns represent groups.  $H_0$  corresponds to the assumption that all groups have the same proportion of 1's.

With the /T flag, it displays the results in a table that contains the number of rows, the number of columns, the Cochran statistic, the critical value, and the conclusion (1 to accept  $H_0$  and 0 to reject it).

V\_flag will be set to -1 for any error and to zero otherwise.

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsFriedmanTest**.

## StatsContingencyTable

### StatsContingencyTable [ *flags* ] srcWave

The StatsContingencyTable operation performs contingency table analysis on 2D and 3D tables. Output is to the W\_ContingencyTableResults wave in the current data folder or optionally to a table or the history area.

#### Flags

/ALPH = *val* Sets the significance level (default *val*=0.05).  
 /COR=*mode* Sets the correction type for 2x2 tables. By default there is no correction. Use *mode*=1 for Yates and *mode*=2 for Haber correction.  
 /FEXT={*row, col*} Computes Fisher's Exact P-value with 2x2 contingency tables. *row* and *col* are zero-based indices of the table entry where it computes the probability of getting the results in the table or more extreme values. Without the /Q flag, it prints the probabilities of each individual table in the history.  
 Given the contingency table:

	Succeeded	Failed
Group1	11	8
Group2	4	9

Example 1: When you use /FEXT={0, 0} the P-value represents the sum of the probabilities of the first group having in the Succeeded column 11 or more extreme values, i.e., 12, 13, 14, and 15. In each case the remaining table elements are adjusted so that row and column sums remain constant.

Example 2: When you needed to evaluate the sum of the probabilities of Group2 having 4 counts or less in the Succeeded column, then the appropriate flag is /FEXT={1, 1}, which effectively computes the equivalent of having 9, 10, 11, 12, and 13 Failed counts. In each case it computes the upper, the lower, and the two-tail probabilities.

/HTRG Tests for heterogeneity between tables stored as layers of 3D wave.  
 /LLIK Computes log likelihood statistic.  
 /Q No results printed in the history area.  
 /T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.  
*k*=0: Normal with dialog (default).  
*k*=1: Kills with no dialog.  
*k*=2: Disables killing.

The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results unless you moved the output wave to a different data folder. If the named table exists but it does not display the output wave from the current data folder, the table is renamed and a new table is created.

/Z Ignores errors. V\_flag will be set to -1 for any error and to zero otherwise.

#### Details

StatsContingencyTable supports 2D waves representing single contingency tables or 3D waves representing multiple 2D tables (where each table is a layer) or a single 3D table. Each entry in the wave must contain a frequency value and must be a positive number; it does not support 0's, NaNs, or INFs. In the special case of 2x2 tables, use the /COR flag to compute the statistic using either the Yates or Haber corrections. Except for the heterogeneity option you can also compute the log likelihood statistic. In all the tests,  $H_0$  corresponds to independence between the tested variables.

For 3D tables StatsContingencyTable provides Chi-squared, degrees of freedom, the critical value, and optionally the log likelihood G statistic (/LLIK flag) for each of the following cases:

1. Mutual independence by testing if all three variables are independent of each other.

## StatsCorrelation

---

2. Partial dependence (rows) by testing if rows independent of columns and layers.
3. Partial dependence (columns) by testing if columns independent of rows and layers.
4. Partial dependence (layers) by testing if layers independent of rows and columns.

In each case you should compare the statistic with the critical value and reject  $H_0$  if the statistic exceeds or equals the critical value.

You should examine the table entries to determine if the Chi-square statistic is appropriate (if the frequency is smaller than 6 for  $\alpha=0.05$  you should consider computing the Fisher exact test).

V\_flag will be set to -1 for any error and to zero otherwise.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsInvChiCDF**.

## StatsCorrelation

### **StatsCorrelation(waveA [, waveB])**

The StatsCorrelation function computes Pearson's correlation coefficient between two real valued arrays of data of the same length. Pearson r is give by:

$$r = \frac{\sum_{i=0}^{n-1} (waveA[i]-A)(waveB[i]-B)}{\sqrt{\sum_{i=0}^{n-1} (waveA[i]-A)^2 \sum_{i=0}^{n-1} (waveB[i]-B)^2}}$$

Here  $A$  is the average of the elements in  $waveA$ ,  $B$  is the average of the elements of  $waveB$  and the sum is over all wave elements.

### Details

If you use both  $waveA$  and  $waveB$  then the two waves must have the same number of points but they could be of different number type. If you use only the  $waveA$  parameter then  $waveA$  must be a 2D wave. In this case StatsCorrelation will return 0 and create a 2D wave M\_Pearson where the  $(i,j)$  element is Pearson's r corresponding to columns  $i$  and  $j$ .

Fisher's z transformation converts Person's r above to a normally distributed variable z:

$$z = \frac{1}{2} \ln\left(\frac{1+r}{1-r}\right) \text{ with a standard error } \sigma_z = \frac{1}{\sqrt{n-3}}.$$

You can convert between the two representations using the following functions:

```
Function pearsonToFisher(inr)
  Variable inr
  return 0.5*(ln(1+inr)-ln(1-inr))
End
Function fisherToPearson(inz)
  Variable inz
  return tanh(inz)
End
```

## StatsDExpCDF

### **StatsDExpCDF(x, m, s)**

The StatsDExpCDF function returns the double-exponential cumulative distribution function

$$F(x, \mu, \sigma) = \begin{cases} \exp\left(\frac{x-\mu}{\sigma}\right) & \text{when } x < \mu \\ 1 - \frac{1}{2} \exp\left(-\left|\frac{x-\mu}{\sigma}\right|\right) & \text{when } x \geq \mu \end{cases}$$

for  $\sigma > 0$ . It returns NaN when  $\sigma = 0$ .

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsDExpPDF** and **StatsInvDExpCDF**.

**StatsDExpPDF****StatsDExpPdf(x, m, s)**

The StatsDExpPdf function returns the double-exponential probability distribution function

$$f(x, \mu, \sigma) = \frac{1}{2\sigma} \exp\left[-\left|\frac{x - \mu}{\sigma}\right|\right]$$

where  $\mu$  is the location parameter and  $\sigma > 0$  is the scale parameter. Use  $\mu=0$  and  $\sigma=1$  for the standard form of the double exponential distribution. It returns NaN when  $\sigma=0$ .

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsDExpCDF** and **StatsInvDExpCDF**.

**StatsDIPTest****StatsDIPTest [/Z] srcWave**

The StatsDIPTest operation performs Hartigan test for unimodality.

**Flags**

/Z            Ignores errors. V\_flag will be set to -1 for any error and to zero otherwise.

**Details**

The input to the operation *srcWave* is any real numeric wave. Outputs are: V\_Value contains the dip statistic; V\_min is the lower end of the modal interval; and V\_max is the higher end of the modal interval. Percentage points or critical values for the dip statistic can be obtained from simulations using an identical sample size as in this example:

```
Function getCriticalValue(sampleSize,alpha)
Variable sampleSize,alpha
  Make/O/N=(sampleSize) dataWave
  Make/O/N=100000 dipResults
  Variable i
  for(i=0;i<100000;i+=1)
    dataWave=enoise(100)
    StatsDipTest dataWave
    dipResults[i]=V_Value
  endfor
  Histogram/P/B=4 dipResults                    // Compute the PDF.
  Wave W_Histogram
  Integrate/METH=1 W_Histogram/D=W_INT        // Compute the CDF.
  Findlevel/Q W_int,(1-alpha)                 // Find the critical value.
  return V_LevelX
End
```

**References**

**See Also**

Chapter III-12, **Statistics** for a function and operation overview.

**StatsDunnTest****StatsDunnTest [flags] [wave1, wave2,... wave100]**

The StatsDunnTest operation performs the Dunn test by comparing multiple groups to a control group. Output is to the M\_DunnTestResults wave in the current data folder or optionally to a table. StatsDunnTest usually follows StatsANOVA1Test.

**Flags**

/ALPH = val            Sets the significance level (default val=0.05).  
 /CIDX=cIndex         Specifies the (zero based) index of the input wave corresponding to the control group.  
                       The default is zero (the first wave corresponds to the control group).

## StatsErlangCDF

---

/Q	No results printed in the history area.
/SWN	Creates a text wave, T_DunnettDescriptors, containing wave names corresponding to each row of the comparison table (Save Wave Names). Use /T to append the text wave to the last column.
/T= <i>k</i>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing.
/TAIL= <i>tc</i>	Specifies $H_0$ . <i>tc</i> =1: Default; one tailed test ( $\mu_c \leq \mu_a$ ). <i>tc</i> =2: One tailed test ( $\mu_c \geq \mu_a$ ). <i>tc</i> =4: Two tailed test ( $\mu_c = \mu_a$ ). Code combinations are not allowed.
/WSTR= <i>waveListString</i>	Specifies a string containing a semicolon-separated list of waves that contain sample data. Use <i>waveListString</i> instead of listing each wave after the flags.
/Z	Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

### Details

StatsDunnettTest inputs are two or more 1D numeric waves (one wave for each group of samples). The input waves may contain different number of points, but they must contain two or more valid entries per wave.

For output to a table (using /T), each labelled row represents the results of the test for comparing the means of one group to the control group, and rows are ordered so that all comparisons are computed sequentially starting with the group having the smallest mean. The contents of the labelled columns are: the first contains the difference between the group means; the second contains SE (which is computed for possibly unequal number of points); the third contains the *q* statistic for the pair which may be positive or negative; the fourth column contains the critical *q'* value; and the fifth contains 0 if the conclusion is to reject  $H_0$  or 1 for accepting  $H_0$ .

V\_flag will be set to -1 for any error and to zero otherwise.

## StatsErlangCDF

### StatsErlangCDF(*x*, *b*, *c*)

The StatsErlangCDF function returns the Erlang cumulative distribution function

$$F(x, b, c) = 1 - \frac{\Gamma\left(c, \frac{x}{b}\right)}{\Gamma(c)}$$

where  $b > 0$  (also as  $\lambda = 1/b$ ) is the scale parameter,  $c > 0$  the shape parameter,  $\Gamma(x)$  the **gamma** function, and  $\Gamma(a, x)$  the incomplete gamma function **gammaInc**.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsErlangPDF**.

## StatsErlangPDF

### StatsErlangPDF(*x*, *b*, *c*)

The StatsErlangPDF function returns the Erlang probability distribution function

$$f(x, b, c) = \frac{\left(\frac{x}{b}\right)^{c-1} \exp\left(-\frac{x}{b}\right)}{b(c-1)!} \text{ where } b > 0 \text{ (also as } \lambda = 1/b \text{) is the scale parameter and } c > 0 \text{ the shape parameter.}$$

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsErlangCDF**.

## StatsErrorPDF

### **StatsErrorPDF(x, a, b, c)**

The StatsErrorPDF function returns the error probability distribution function or the exponential power distribution

$$f(x, a, b, c) = \frac{\exp\left[-\frac{1}{2}\left(\frac{|x-a|}{b}\right)^c\right]}{b2^{\frac{c}{2}}\Gamma\left(1+\frac{c}{2}\right)}$$

where  $a$  is the location parameter,  $b > 0$  is the scale parameter,  $c > 0$  is the shape parameter, and  $\Gamma(x)$  is the **gamma** function.

### See Also

Chapter III-12, **Statistics** for a function and operation overview.

## StatsEValueCDF

### **StatsEValueCDF(x, μ, σ)**

The StatsEValueCDF function returns the extreme-value (type I, Gumbel) cumulative distribution function

$$F(x, \mu, \sigma) = 1 - \exp\left(-\exp\left(\frac{x - \mu}{\sigma}\right)\right)$$

where  $\sigma > 0$ . This is also known as the “minimum” form or distribution of the smallest extreme. To obtain the distribution of the largest extreme reverse the sign of  $\sigma$ .

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsEValuePDF** and **StatsInvEValueCDF**.

## StatsEValuePDF

### **StatsEValuePDF(x, μ, σ)**

The StatsEValuePDF function returns the extreme-value (type I, Gumbel) probability distribution function

$$f(x, \mu, \sigma) = \frac{1}{\sigma} \exp\left(\frac{x - \mu}{\sigma}\right) \exp\left(-\exp\left(\frac{x - \mu}{\sigma}\right)\right)$$

where  $\sigma > 0$ . This is also known as the “minimum” form or the distribution of the smallest extreme. To obtain the distribution of the largest extreme reverse the sign of  $\sigma$ .

## StatsFPDF

### **StatsFPDF(x, n1, n2)**

The StatsFPDF function returns the probability distribution function for the F distribution with shape parameters  $n1$  and  $n2$

$$f(x, n_1, n_2) = \frac{\Gamma\left(\frac{n_1 + n_2}{2}\right) \left(\frac{n_1}{n_2}\right)^{\frac{n_1}{2}} x^{\frac{n_1}{2} - 1}}{\Gamma\left(\frac{n_1}{2}\right) \Gamma\left(\frac{n_2}{2}\right) \left(1 + \frac{n_1 x}{n_2}\right)^{\frac{n_1 + n_2}{2}}}$$

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsFCDF** and **StatsInvFCDF**.

## StatsFriedmanCDF

### **StatsFriedmanCDF(x, n, m, method, useTable)**

The StatsFriedmanCDF function returns the cumulative probability distribution of the Friedman distribution with  $n$  rows and  $m$  columns. The exact Friedman distribution is computationally intensive, taking on the order of  $(n!)^m$  iterations. You may be able to use a range of precomputed exact values by passing a nonzero value for *useTable*, which will use *method* only if the value is not in the table. For large  $m$ , consider using the Chi-squared or the Monte-Carlo approximations. To abort execution, press Command-period (*Macintosh*) or Ctrl+Break (*Windows*).

<i>method</i>	What It Does
0	Exact computation.
1	Chi-square approximation.
2	Monte-Carlo approximation.
3	Use built-table only and return NaN if not in table.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsInvFriedmanCDF** and **StatsFriedmanTest**.

## StatsFriedmanTest

**StatsFriedmanTest** [*flags*] [*wave1*, *wave2*,... *wave100*]

The StatsFriedmanTest operation performs Friedman's test on a randomized block of data. It is a nonparametric analysis of data contained in either individual 1D waves or in a single 2D wave. Output is to the M\_FriedmanTestResults wave in the current data folder or optionally to a table.

### Flags

/ALPH = <i>val</i>	Sets the significance level (default <i>val</i> =0.05).
/Q	No results printed in the history area.
/RW	Saves the ranking wave M_FriedmanRanks, which contains the rank values corresponding to each input datum.
/T= <i>k</i>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing. The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results.
/WSTR= <i>waveListString</i>	Specifies a string containing a semicolon-separated list of waves that contain sample data. Use <i>waveListString</i> instead of listing each wave after the flags.
/Z	Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

### Details

The Friedman test ranks the input data on a row-by-row basis, sums the ranks for each column, and computes the Friedman statistic, which is proportional to the sum of the squares of the ranks.

Input waves can be a single 2D wave or a list of 1D numeric waves, which can also be specified in a string list with /WSTR. All 1D waves must have the same number of points. A 2D wave must not contain any NaNs.

The critical value for the Friedman distribution is fairly difficult to compute when the number of rows and columns is large because it requires a number of permutations on the order of  $(\text{numColumns!})^{\text{numRows}}$ . A certain range of these critical values are supported by precomputed tables. When the exact critical value is not available you can use one of the two approximations that are always computed: the Chi-squared approximation or the Iman and Davenport approximation, which converts the Friedman statistic is converted to a new value *Ff* then compares it with critical values from the F distribution using weighted degrees of freedom.

With the /T flag, it displays the results in a table that contains the number of rows, the number of columns, the Friedman statistic, the exact critical value (if available), the Chi-squared approximation, the Iman and Davenport approximation, and the conclusion (1 to accept  $H_0$  and 0 to reject it).

V\_flag will be set to -1 for any error and to zero otherwise.

## StatsFTest

**StatsFTest** [*flags*] *wave1*, *wave2*

The StatsFTest operation performs the F-test on the two distributions in *wave1* and *wave2*, which can be any real numeric type, must contain at least two data points each, and can have an arbitrary number of dimensions. Output is to the W\_StatsFTest wave in the current data folder or optionally to a table.

### Flags

/ALPH = <i>val</i>	Sets the significance level (default <i>val</i> =0.05).
/Q	No results printed in the history area.
/T= <i>k</i>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed.

## StatsGammaCDF

---

	$k=0$ :	Normal with dialog (default).
	$k=1$ :	Kills with no dialog.
	$k=2$ :	Disables killing.
/TAIL= $tc$		Specifies the tail tested.
	$tc=1$ :	Lower one-tail test with $H_a$ : $\sigma_1 > \sigma_2$ .
	$tc=2$ :	Upper one-tail test with $H_a$ : $\sigma_1 < \sigma_2$ .
	$tc=4$ :	Default; the null hypothesis $H_0$ : $\sigma_1 = \sigma_2$ with $H_a$ : $\sigma_1 \neq \sigma_2$ .
/Z		Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

### Details

The F statistic is the ratio of the variance of *wave1* to the variance of *wave2*. We assume the waves have equal wave variances and that  $H_0$  is  $\sigma_1 = \sigma_2$ . For the upper one-tail test we reject  $H_0$  if F is greater than the upper critical value or if F is smaller than the lower critical value in the lower one-tail test. In the two-tailed test we reject  $H_0$  if F is either greater than the upper critical value or smaller than the lower critical value. The critical values are computed by numerically solving for the argument at which the cumulative distribution function (CDF) equals the appropriate values for the tests. The CDF is given by

$$F(x, n_1, n_2) = 1 - \text{betain}\left(\frac{n_2}{2}, \frac{n_1}{2}, \frac{n_2}{n_2 + n_1 x}\right)$$

where the degrees of freedom  $n_1$  and  $n_2$  equal the number of valid (non-NaN) points in each wave -1, and *betain* is the incomplete beta function. To get the critical value for the upper one-tail test we solve  $F(x) = 1 - \alpha$ . For the lower one-tail test we solve  $F(x) = \alpha$ . In the two-tailed test the lower critical value is a solution for  $F(x) = \alpha/2$  and the upper critical value is a solution for  $F(x) = 1 - \alpha/2$ .

The F-test requires that the two samples are from normally distributed populations.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsVariancesTest**, **StatsFCDF**, and **betain**.

## StatsGammaCDF

### StatsGammaCDF(*x*, $\mu$ , $\sigma$ , $\gamma$ )

The StatsGammaCDF function returns the gamma cumulative distribution function

$$F(x, \mu, \sigma, \gamma) = \frac{\Gamma_{inc}\left(\gamma, \frac{x - \mu}{\sigma}\right)}{\Gamma(\gamma)}, \quad \begin{array}{l} x \geq \mu \\ \sigma, \gamma > 0 \end{array}$$

where  $\Gamma$  is the gamma function and  $\Gamma_{inc}$  is the incomplete gamma function **gammaInc**.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsGammaPDF** and **StatsInvGammaCDF**.

## StatsGammaPDF

### StatsGammaPDF(*x*, $\mu$ , $\sigma$ , $\gamma$ )

The StatsGammaPDF function returns the gamma probability distribution function

$$f(x, \mu, \sigma, \gamma) = \frac{\left(\frac{x - \mu}{\sigma}\right)^{\gamma-1} \exp\left(-\frac{x - \mu}{\sigma}\right)}{\sigma \Gamma(\gamma)}, \quad \begin{array}{l} x \geq \mu \\ \sigma, \gamma > 0 \end{array}$$

where  $\mu$  is the location parameter,  $\sigma$  is the scale parameter,  $\gamma$  is the shape parameter, and  $\Gamma$  is the gamma function.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsGammaCDF** and **StatsInvGammaCDF**.

## StatsGeometricCDF

### StatsGeometricCDF(*x*, *p*)

The StatsGeometricCDF function returns the geometric cumulative distribution function

$F(x,p) = 1 - (1-p)^{x+1}$  where  $p$  is the probability of success in a single trial and  $x$  is the number of trials for  $x \geq 0$ .

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsGeometricPDF** and **StatsInvGeometricCDF**.

## StatsGeometricPDF

### StatsGeometricPDF(*x*, *p*)

The StatsGeometricPDF function returns the geometric probability distribution function

$F(x,p) = p(1-p)^x$  where the  $p$  is the probability of success in a single trial and  $x$  is the number of trials  $x \geq 0$ .

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsGeometricCDF** and **StatsInvGeometricCDF**.

## StatsHodgesAjneTest

### StatsHodgesAjneTest [*flags*] *srcWave*

The StatsHodgesAjneTest operation performs the Hodges-Ajne nonparametric test for uniform distribution around a circle. Output is to the W\_HodgesAjne wave in the current data folder or optionally to a table.

#### Flags

- /ALPH = *val*      Sets the significance level (default *val*=0.05).
- /Q                    No results printed in the history area.
- /SA=*specAngle*    Uses the Batschelet modification of the Hodges-Ajne test to test for uniformity against the alternative of concentration around the specified angle. *specAngle* must be expressed in radians modulus  $2\pi$ .
- /T=*k*                Displays results in a table. *k* specifies the table behavior when it is closed.
  - k*=0:    Normal with dialog (default).
  - k*=1:    Kills with no dialog.
  - k*=2:    Disables killing.
- /Z                    Ignores errors. V\_flag will be set to -1 for any error and to zero otherwise.

#### Details

The input *srcWave* must contain angles in radians, can be any number of dimensions, can be single or double precision, and should not contain NaNs or INFs.

StatsHodgesAjneTest performs the standard Hodges-Ajne test, which simply tests for uniformity against the hypothesis that the population is not uniformly distributed around the circle. This test finds a diameter that divides the circle into two halves such that one contains the least number of data  $m$ , the test statistic.

Use /SA to perform the modified (Batschelet) test, which tests against the alternative that the population is concentrated somehow about the specified angle. The modified test counts the number of points  $m'$  in 90-degree neighborhoods around the specified angle. The test statistic is given by  $C=n-m'$  where  $n$  is the number of points in the wave. The critical value is computed from the binomial probability density.

In both cases  $H_0$  is rejected if the statistic is smaller than the critical value.

V\_flag will be set to -1 for any error and to zero otherwise.

## StatsHyperGCDF

---

### See Also

Chapter III-12, **Statistics** for a function and operation overview.

**StatsCircularMeans**, **StatsCircularMoments**, **StatsWatsonUSquaredTest**, **StatsWatsonWilliamsTest**, and **StatsWheelerWatsonTest**.

## StatsHyperGCDF

### **StatsHyperGCDF**(*x*, *m*, *n*, *k*)

The **StatsHyperGCDF** function returns the hypergeometric cumulative distribution function, which is the probability of getting *x* marked items when drawing (without replacement) *k* items out of a population of *m* items when *n* out of the *m* are marked.

### Details

The hypergeometric distribution is

$$F(x, m, n, k) = \sum_{L=0}^x \frac{\binom{n}{L} \binom{m-L}{k-L}}{\binom{m}{k}}$$

where  $\binom{a}{b}$  is the **binomial** function. All parameters must be positive integers and must have  $m > n$  and  $x < k$ ; otherwise it returns NaN.

### References

Chapter III-12, **Statistics** for a function and operation overview; **StatsHyperGPDF**.

## StatsHyperGPDF

### **StatsHyperGPDF**(*x*, *m*, *n*, *k*)

The **StatsHyperGPDF** function returns the hypergeometric probability distribution function, which is the probability of getting *x* marked items when drawing without replacement *k* items out of a population of *m* items where *n* out of the *m* are marked.

### Details

The hypergeometric distribution is

$$f(x, m, n, k) = \frac{\binom{n}{x} \binom{m-n}{k-x}}{\binom{m}{k}}$$

where  $\binom{a}{b}$  is the **binomial** function. All parameters must be positive integers and must have  $m > n$  and  $x < k$ .

## StatsInvBetaCDF

### **StatsInvBetaCDF**(*cdf*, *p*, *q* [, *a*, *b*])

The **StatsInvBetaCDF** function returns the inverse of the beta cumulative distribution function. There is no closed form expression for the inverse beta CDF; it is evaluated numerically.

The defaults ( $a=0$  and  $b=1$ ) correspond to the standard beta distribution.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsBetaCDF** and **StatsBetaPDF**.

**StatsInvBinomialCDF****StatsInvBinomialCDF(cdf, p, N)**

The StatsInvBinomialCDF function returns the inverse of the binomial cumulative distribution function. The inverse function returns the value at which the binomial CDF with probability  $p$  and total elements  $N$ , has the value 0.95. There is no closed form expression for the inverse binomial CDF; it is evaluated numerically.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsBinomialCDF** and **StatsBinomialPDF**.

**StatsInvCauchyCDF****StatsInvCauchyCDF(cdf, μ, σ)**

The StatsInvCauchyCDF function returns the inverse of the Cauchy-Lorentz cumulative distribution function

$$x = \mu + \sigma \tan \left[ \pi \left( cdf - \frac{1}{2} \right) \right]$$

It returns NaN for  $cdf < 0$  or  $cdf > 1$ .

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsCauchyCDF** and **StatsCauchyPDF**.

**StatsInvChiCDF****StatsInvChiCDF(x, n)**

The StatsInvChiCDF function returns the inverse of the chi-squared distribution of  $x$  and shape parameter  $n$ . The inverse of the distribution is also known as the percent point function.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsChiCDF** and **StatsChiPDF**.

**StatsInvCMSSDCDF****StatsInvCMSSDCDF(cdf, n)**

The StatsInvCMSSDCDF function returns the critical values of the C distribution (mean square successive difference), which is

$$f(C, n) = \frac{\Gamma(2m+2)}{a^{2^{2m+1}} [\Gamma(m+1)]^2} \left( 1 - \frac{C^2}{a^2} \right)^m \quad \text{where} \quad a^2 = \frac{(n^2 + 2n - 12)(n - 2)}{(n^2 - 13n + 24)}, \quad m = \frac{(n^4 - n^3 - 13n^2 + 37n - 60)}{2(n^2 - 13n + 24)}.$$

Critical values are computed from the integral of the probability distribution function.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsCMSSDCDF** and **StatsSRTest**.

**StatsInvDExpCDF****StatsInvDExpCdf(cdf, μ, σ)**

The StatsInvDExpCdf function returns the inverse of the double-exponential cumulative distribution function

$$\begin{aligned} \mu + \sigma \ln(2cdf) & \quad cdf < 0.5 \\ \mu - \sigma \ln(2(1 - cdf)) & \quad cdf \geq 0.5 \end{aligned}$$

## StatsInvEValueCDF

---

It returns NaN for  $cdf < 0$  or  $cdf > 1$ .

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsDExpCDF** and **StatsDExpPDF**.

## StatsInvEValueCDF

### **StatsInvEValueCDF(*cdf*, $\mu$ , $\sigma$ )**

The StatsInvEValueCDF function returns the inverse of the extreme-value (type I, Gumbel) cumulative distribution function  $x = \mu + \sigma \ln[-\ln(1-cdf)]$  where  $\sigma > 0$ . It returns NaN for  $cdf < 0$  or  $cdf > 1$ . This inverse applies to the "minimum" form of the distribution. Reverse the sign of  $\sigma$  to obtain the inverse distribution of the maximum form.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsEValueCDF** and **StatsEValuePDF**.

## StatsInvExpCDF

### **StatsInvExpCDF(*cdf*, $\mu$ , $\sigma$ )**

The StatsInvExpCDF function returns the inverse of the exponential cumulative distribution function  $x = \mu - \sigma \ln(1-cdf)$ .

It returns NaN for  $cdf < 0$  or  $cdf > 1$ .

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsExpCDF** and **StatsExpPDF**.

## StatsInvFCDF

### **StatsInvFCDF(*x*, *n1*, *n2*)**

The StatsInvFCDF function returns the inverse of the F distribution cumulative distribution function for  $x$  and shape parameters  $n1$  and  $n2$ . The inverse is also known as the percent point function.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsFCDF** and **StatsFPDF**.

## StatsInvFriedmanCDF

### **StatsInvFriedmanCDF(*cdf*, *n*, *m*, *method*, *useTable*)**

The StatsInvFriedmanCDF function returns the inverse of the Friedman distribution cumulative distribution function of  $cdf$  with  $n$  rows and  $m$  columns. Use this typically to compute the critical values of the distribution

```
Print StatsInvFriedmanCDF(1-alpha,n,m,0,1)
```

where alpha is the significance level of the associated test.

The complexity of the computation of Friedman CDF is on the order of  $(n!)^m$ . For nonzero values of *useTable*, searches are limited to the built-in table for distribution values. If  $n$  and  $m$  are not in the table the calculation may still proceed according to the *method*.

<i>method</i>	What It Does
0	Exact computation(slow, not recommended).
1	Chi-square approximation.
2	Monte-Carlo approximation (slow).
3	Use built-in table only and return a NaN if not in table.

For large  $m$  and  $n$ , consider using the Chi-squared or the Iman and Davenport approximations. To abort execution, press Command-period (*Macintosh*) or Ctrl+Break (*Windows*).

**Note:** Table values are different from computed values for both methods. Table values use more conservative criteria than computed values. Table values are more consistent with published values because the Friedman distribution is a highly irregular function with multiple steps of arbitrary sizes. The standard for published tables provides the X value of the next vertical transition to the one on which the specified P is found.

Precomputed tables use these values:

<i>n</i>	<i>m</i>
3	2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16
4	2, 3, 4, 5, 6, 7, 8, 9
5	2, 3, 4, 5, 6
6	2, 3, 4, 5
7	2, 3, 4
8	2, 3
9	2, 3

Chapter III-12, **Statistics** for a function and operation overview; **StatsFriedmanCDF** and **StatsFriedmanTest**.

## StatsInvGammaCDF

### **StatsInvGammaCDF**(cdf, $\mu$ , $\sigma$ , $\gamma$ )

The StatsInvGammaCDF function returns the inverse of the gamma cumulative distribution function. There is no closed form expression for the inverse gamma distribution; it is evaluated numerically.

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsGammaCDF** and **StatsGammaPDF**.

## StatsInvGeometricCDF

### **StatsInvGeometricCDF**(cdf, $p$ )

The StatsInvGeometricCDF function returns the inverse of the geometric cumulative distribution function

$$x = \frac{\ln(1 - \text{cdf})}{\ln(1 - p)} - 1 \text{ where } p \text{ is the probability of success in a single trial and } x \text{ is the number of trials.}$$

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsGeometricCDF** and **StatsGeometricPDF**.

## StatsInvKuiperCDF

### **StatsInvKuiperCDF**(cdf)

The StatsInvKuiperCDF function returns the inverse of Kuiper cumulative distribution function.

There is no closed form expression. It is mapped to the range of 0.4 to 4, with accuracy of 1e-10.

#### References

See in particular Section 14.3 of

Press, William H., et al., *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992.

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsKuiperCDF**.

### StatsInvLogisticCDF

**StatsInvLogisticCDF(cdf, a, b)**

The StatsInvLogisticCDF function returns the inverse of the logistic cumulative distribution function

$x = a + b \log\left(\frac{cdf}{1-cdf}\right)$  where the scale parameter  $b > 0$  and the shape parameter is  $a$ .

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsLogisticCDF** and **StatsLogisticPDF** functions.

### StatsInvLogNormalCDF

**StatsInvLogNormalCDF(cdf, μ, σ, γ)**

The StatsInvLogNormalCDF function returns the numerically evaluated inverse of the lognormal cumulative distribution function.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsLogNormalCDF** and **StatsLogNormalPDF** functions.

### StatsInvMaxwellCDF

**StatsInvMaxwellCDF(cdf, k)**

The StatsInvMaxwellCDF function returns the evaluated numerically inverse of the Maxwell cumulative distribution function. There is no closed form expression.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsMaxwellCDF** and **StatsMaxwellPDF** functions.

### StatsInvMooreCDF

**StatsInvMooreCDF(cdf, N)**

The StatsInvMooreCDF function returns the inverse cumulative distribution function for Moore's  $R^*$ , which is used as a critical value in nonparametric version of the Rayleigh test for uniform distribution around the circle. It supports the range  $3 \leq N \leq 120$  and does not change appreciably for  $N > 120$ .

The inverse distribution is computed from polynomial approximations derived from simulations and should be accurate to approximately three significant digits.

**References**

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsCircularMeans** function.

### StatsInvNBinomialCDF

**StatsInvNBinomialCDF(cdf, k, p)**

The StatsInvNBinomialCDF function returns the numerically evaluated inverse of the negative binomial cumulative distribution function. There is no closed form expression.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNBinomialCDF** and **StatsNBinomialPDF** functions.

### StatsInvNCChiCDF

**StatsInvNCChiCDF(cdf, n, d)**

The StatsInvNCChiCDF function returns the inverse of the noncentral chi-squared cumulative distribution function. It is computationally intensive because the inverse is computed numerically and involves multiple evaluations of the noncentral distribution, which is evaluated from a series expansion.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNCChiCDF**, **StatsNCChiPDF**, **StatsChiCDF**, and **StatsChiPDF** functions.

**StatsInvNCFCDF****StatsInvNCFCDF(*cdf*, *n1*, *n2*, *d*)**

The StatsInvNCFCDF function returns the numerically evaluated inverse of the cumulative distribution function of the noncentral F distribution. *n1* and *n2* are the shape parameters and *d* is the noncentrality measure. There is no closed form expression for the inverse.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNCFCDF** and **StatsNCFPDF** functions.

**StatsInvNormalCDF****StatsInvNormalCDF(*cdf*, *m*, *s*)**

The StatsInvNormalCDF function returns the numerically computed inverse of the normal cumulative distribution function. There is no closed form expression.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNormalCDF** and **StatsNormalPDF** functions.

**StatsInvParetoCDF****StatsInvParetoCDF(*cdf*, *a*, *c*)**

The StatsInvParetoCDF function returns the inverse of the Pareto cumulative distribution function

$$x = \frac{a}{(1 - cdf)^{(1/c)}}$$

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsParetoCDF** and **StatsParetoPDF** functions.

**StatsInvPoissonCDF****StatsInvPoissonCDF(*cdf*, *λ*)**

The StatsInvPoissonCDF function returns the numerically evaluated inverse of the Poisson cumulative distribution function. There is no closed form expression for the inverse Poisson distribution.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsPoissonCDF** and **StatsPoissonPDF** functions.

**StatsInvPowerCDF****StatsInvPowerCDF(*cdf*, *b*, *c*)**

The StatsInvPowerCDF function returns the inverse of the Power Function cumulative distribution function  $x = b/cdf^{(1/c)}$  where the scale parameter *b* and the shape parameter *c* satisfy  $b, c > 0$ .

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsPowerCDF** and **StatsPowerPDF** functions.

**StatsInvQCDF****StatsInvQCDF(*cdf*, *r*, *c*, *df*)**

The StatsInvQCDF function returns the critical value of the Q cumulative distribution function for *r* the number of groups, *c* the number of treatments, and *df* the error degrees of freedom ( $df = r * c * (n - 1)$  with sample size *n*).

## StatsInvQpCDF

---

### Details

The Q distribution is the maximum of several Studentized range statistics. For a simple Tukey test, use  $r=1$ .

### Examples

The critical value for a Tukey test comparing 5 treatments with 6 samples and 0.05 significance is:

```
Print StatsInvQpCDF(1-0.05,1,5,5*(6-1))
```

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsTukeyTest** function.

## StatsInvQpCDF

### **StatsInvQpCDF**(*ng*, *nt*, *df*, *alpha*, *side*, *sSizeWave*)

The **StatsInvQpCDF** function returns the critical value of the Q' cumulative distribution function for *ng* the number of groups, *nt* the number of treatments, and *df* the error degrees of freedom. *side*=1 for upper-tail or *side*=2 for two-tailed critical values.

*sSizeWave* is an integer wave of *ng* columns and *nt* rows specifying the number of samples in each treatment. If *sSizeWave* is a null wave (\$" ") **StatsInvQpCDF** computes the number of samples from  $df=ng*nt*(n-1)$  with *n* truncated to an integer.

### Details

**StatsInvQpCDF** is a modified Q distribution typically used with Dunnett's test, which compares the various means with the mean of the control group or treatment.

**StatsInvQpCDF** differs from other **StatsInvXXX** functions in that you do not specify a *cdf* value for the inverse (usually  $1-\alpha$  for the critical value). Here *alpha* selects one- or two-tailed critical values.

It is computationally intensive, taking longer to execute for smaller *alpha* values.

### Examples

The critical value for a Dunnett test comparing 4 treatments with 4 samples and (upper tail) 0.05 significance is:

```
// here n=4 because 12=1*4*(4-1).
Print StatsInvQpCDF(1,4,12,0.05,1,$" ")
  2.28734
```

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsDunnettTest** and **StatsInvQpCDF** functions.

## StatsInvRayleighCdf

### **StatsInvRayleighCdf**(*cdf* [, *s* [, *m*]])

The **StatsInvRayleighCdf** function returns the inverse of the Rayleigh cumulative distribution function  $x = \mu + \sigma\sqrt{-2\ln(1-cdf)}$  with defaults *s*=1 and *m*=0. It returns NaN for  $s \leq 0$  and zero for  $x \leq m$ .

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRayleighCDF** and **StatsRayleighPDF** functions.

## StatsInvRectangularCDF

### **StatsInvRectangularCDF**(*cdf*, *a*, *b*)

The **StatsInvRectangularCDF** function returns the inverse of the rectangular (uniform) cumulative distribution function  $x = a + cdf(b-a)$  where  $a < b$ .

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRectangularCDF** and **StatsRectangularPDF** functions.

## StatsInvSpearmanCDF

**StatsInvSpearmanCDF(*cdf*, *N*)**

The StatsInvSpearmanCDF function returns the inverse cumulative distribution function for Spearman's  $r$ , which is used as a critical value in rank correlation tests.

The inverse distribution is computed by finding the value of  $r$  for which it attains the  $cdf$  value. The result is usually lower than in published tables, which are more conservative when the first derivative of the distribution is discontinuous.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRankCorrelationTest**, **StatsSpearmanRhoCDF**, and **StatsKendallTauTest** functions.

## StatsInvStudentCDF

**StatsInvStudentCDF(*cdf*, *n*)**

The StatsInvStudentCDF function returns the numerically evaluated inverse of Student cumulative distribution function. There is no closed form expression.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsStudentCDF** and **StatsStudentPDF** functions.

## StatsInvTopDownCDF

**StatsInvTopDownCDF(*cdf*, *N*)**

The StatsInvTopDownCDF function returns the inverse cumulative distribution function for the top-down distribution. For  $3 \leq N \leq 7$  it uses a lookup table CDF and returns the next higher value of  $r$  for which the distribution value is larger than  $cdf$ . For  $8 \leq N \leq 50$  it returns the nearest value for which the built-in distribution returns  $cdf$ . For  $N > 50$  it returns the scaled normal approximation.

Tabulated values are from Iman and Conover who pick as the critical value the very first transition of the distribution following the specified  $cdf$  value. These tabulated values tend to be slightly higher than calculated values for  $7 < N < 15$ .

### References

Iman, R.L., and W.J. Conover, A measure of top-down correlation, *Technometrics*, 29, 351-357, 1987.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRankCorrelationTest** and **StatsTopDownCDF** functions.

## StatsInvTriangularCDF

**StatsInvTriangularCDF(*cdf*, *a*, *b*, *c*)**

The StatsInvTriangularCDF function returns the inverse of the triangular cumulative distribution function

$$x = \begin{cases} a + \sqrt{cdf(b-a)(c-a)} & 0 \leq cdf \leq \frac{c-a}{b-a} \\ b - \sqrt{(1-cdf)(b-a)(b-c)} & \frac{c-a}{b-a} \leq cdf \leq 1 \end{cases}$$

where  $a < c < b$ .

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsTriangularCDF** and **StatsTriangularPDF** functions.

## StatsInvUSquaredCDF

**StatsInvUSquaredCDF(*cdf*, *n*, *m*, *method*, *useTable*)**

The StatsInvUSquaredCDF function returns the inverse of Watson's  $U^2$  cumulative distribution function integer sample sizes  $n$  and  $m$ . Use a nonzero value for *useTable* to search a built-in table of values. If  $n$  and  $m$  cannot be found in the table, it will proceed according to *method*:

## StatsInvVonMisesCDF

---

<i>method</i>	What It Does
0	Exact computation using Burr algorithm (could be slow).
1	Tiku approximation using chi-squared.
2	Use built-in table only and return a NaN if not in table.

---

For large  $n$  and  $m$ , consider using the Tiku approximation. To abort execution, press Command-period (*Macintosh*) or Ctrl+Break (*Windows*). Because  $n$  and  $m$  are interchangeable,  $n$  should always be the smaller value. For  $n > 8$  the upper limit in the table matched the maximum that can be computed using the Burr algorithm. There is no point in using method 0 with  $m$  values exceeding these limits.

The inverse is obtained from precomputed tables of Watson's  $U^2$  (see **StatsUSquaredCDF**).

**Note:** Table values are different from computed values. These values use more conservative criteria than computed values. Table values are more consistent with published values because the  $U^2$  distribution is a highly irregular function with multiple steps of arbitrary sizes. The standard for published tables provides the X value of the next vertical transition to the one on which the specified P is found. See **StatsInvFriedmanCDF**.

## StatsJBTest

### **StatsJBTest [ flags ] srcWave**

The StatsJBTest operation performs the Jarque-Bera test on *srcWave*. Output is to the W\_JBResults wave in the current data folder.

### Flags

/ALPH = *val*      Sets the significance level (default *val*=0.05).

/Q	No results printed in the history area.
/T=k	Displays results in a table. $k$ specifies the table behavior when it is closed. $k=0$ : Normal with dialog (default). $k=1$ : Kills with no dialog. $k=2$ : Disables killing.
/Z	Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

**Details**

StatsJBTest computes the Jarque-Bera statistic

$$JB = \frac{n}{6} \left( S^2 + \frac{K^2}{4} \right)$$

where  $S$  is the skewness,  $K$  is the kurtosis, and  $n$  is the number of points in the input wave. We can express  $S$  and  $K$  terms of the  $j$ th moment of the distribution for  $n$  samples  $X_i$

$$\mu_j = \frac{1}{n} \sum_{i=1}^n (X_i - \bar{X})^j \text{ as } S = \frac{\mu_3}{(\mu_2)^{3/2}} \text{ and } K = \frac{\mu_4}{(\mu_2)^2} - 3.$$

The Jarque-Bera statistic is asymptotically distributed as a Chi-squared with two degrees of freedom. For values of  $n$  in the range [7,2000] the operation provides critical values obtained from Monte-Carlo simulations. For further details or if you would like to run your own simulation to obtain critical values for other values of  $n$ , use the JarqueBeraSimulation example experiment.

StatsJBTest reports the number of finite data points, skewness, kurtosis, Jarque-Bera statistic, asymptotic critical value, and the critical value obtained from Monte-Carlo calculations as appropriate; it ignores NaNs and INFs.

Chapter III-12, **Statistics** for a function and operation overview; **StatsKSTest**, **WaveStats**, and **StatsCircularMoments**.

**StatsKendallTauTest**

**StatsKendallTauTest** [*flags*] *wave1* [, *wave2*]

The StatsKendallTauTest operation performs the nonparametric Mann-Kendall test, which computes a correlation coefficient  $\tau$  (similar to Spearman's correlation) from the relative order of the ranks of the data. Output is to the W\_StatsKendallTauTest wave in the current data folder.

**Flags**

/Q	No results printed in the history area.
/T=k	Displays results in a table. $k$ specifies the table behavior when it is closed. $k=0$ : Normal with dialog (default). $k=1$ : Kills with no dialog. $k=2$ : Disables killing.
/Z	Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

**Details**

Inputs may be a pair of XY (1D) waves of any real numeric type or a single 1D wave, which is equivalent to using a pair of XY waves where the X wave is monotonically increasing function of the point number. StatsKendallTauTest ignores wave scaling.

Kendall's  $\tau$  is 1 for a monotonically increasing input and -1 for monotonically decreasing input. The significance of the test is computed from the normal approximation

$$\text{Var}(\tau) = \frac{4n+10}{9n(n-1)}$$

## StatsKSTest

---

where  $n$  is the number of data points in each wave. The significance is expressed as a P-value for the null hypothesis of no correlation.

### References

Kendall, M.G., *Rank Correlation Methods*, 3rd ed., Griffin, London, 1962.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsRankCorrelationTest**.

For small values of  $n$  you can compute the exact probability using the procedure `WM_KendallSProbability()`.

## StatsKSTest

**StatsKSTest** [*flags*] *srcWave* [, *distWave*]

The StatsKSTest operation performs the Kolmogorov-Smirnov (KS) goodness-of-fit test for two continuous distributions. The first distribution is *srcWave* and the second distribution can be expressed either as the optional wave *distWave* or as a user function with /CDDF. Output is to the W\_KSResults wave in the current data folder.

### Flags

/ALPH = *val*            Sets the significance level (default *val*=0.05).  
/CDDF=*func*            Specifies a user function expressing the cumulative distribution function. See Details.  
/Q                        No results printed in the history area.  
/T=*k*                    Displays results in a table. *k* specifies the table behavior when it is closed.  
                          *k*=0:    Normal with dialog (default).  
                          *k*=1:    Kills with no dialog.  
                          *k*=2:    Disables killing.  
/Z                        Ignores errors. V\_flag will be set to -1 for any error and to zero otherwise.

### Details

The Kolmogorov-Smirnov (KS) goodness-of-fit test applies only to continuous distributions and cases where the compared distribution (expressed as a user function) is completely specified without estimating parameters from the data. It compares the cumulative distribution function (CDF) of two distributions and sets the test statistic D to the largest difference between the CDFs. Because CDFs are in the range [0,1], D is also bound by this range.

When specifying the distributions with two waves, StatsKSTest first sorts the data in the waves and then computes the CDFs and D. You can also specify one of the distributions with a user function. For example, the following function tests if the data in *srcWave* is normally distributed with zero mean and  $\text{stdv}=5$ :

```
Function getUserCDF(inX)
  Variable inX
  return statsNormalCDF(inX,0,5)
End
```

Outputs are the number of elements, the KS statistic D, and the critical value. When both distributions are specified by waves, the number of elements is the weighted value  $(n1*n2)/(n1+n2)$ .

### References

Critical values are based on:

Birnbaum, Z. W., and Fred H. Tingey, One-sided confidence contours for probability distribution functions, *The Annals of Mathematical Statistics*, 22, 592–596, 1951.

A statistically more powerful modification of the classic KS test can be found in:

Khamis, H.J., The two-stage delta-corrected Kolmogorov-Smirnov test, *Journal of Applied Statistics*, 27, 439–450, 2000.

StatsKSTest implements the original KS test. The difficulty in implementing the modified tests for all the cases defined by Stephens is in obtaining the critical values which have to be derived by time consuming Monte-Carlo simulations.

Critiques can be found in:

D'Agostino, R.B., and M. Stephens, eds., *Goodness-Of-Fit Techniques*, Marcel Dekker, New York, 1986.

## StatsKuiperCDF

### StatsKuiperCDF (V)

The StatsKuiperCDF function returns the Kuiper cumulative distribution function

$$F(V) = 1 - 2 \sum_{j=1}^{\infty} (4j^2 V^2 - 1) \exp(-2j^2 V^2)$$

Accuracy is on the order of 1e-15. It returns 0 for values of  $V < 0.4$  or 1 for  $V > 3.1$ .

## StatsKWTest

### StatsKWTest [ flags ] [ wave1, wave2, ... wave100 ]

The StatsKWTest operation performs the nonparametric Kruskal-Wallis test which tests variances using the ranks of the data. Output is to the W\_KWTestResults wave in the current data folder.

#### Flags

- /ALPH = val      Sets the significance level (default val=0.05).
- /E                Computes the exact P-value using the Klotz and Teng algorithm, which may require long computation times for large data sets. You can stop the calculation by pressing Command-period (*Macintosh*) or Ctrl+Break (*Windows*) after which all remaining results remain valid and the exact P-value is set to NaN.
- /Q                No results printed in the history area.
- /T=k             Displays results in a table. k specifies the table behavior when it is closed.
  - k=0:    Normal with dialog (default).
  - k=1:    Kills with no dialog.
  - k=2:    Disables killing.
- /WSTR=waveListString      Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.
- /Z                Ignores errors. V\_flag will be set to -1 for any error and to zero otherwise.

#### Details

Inputs are two or more 1D numerical waves (one for each group of samples). Use NaNs for missing data or use waves with different number of points.

StatsKWTest always computes the critical values using both the Chi-squared and Wallace approximations. If appropriate (small enough data set) you can also use /E to obtain the exact P value. When the calculation involves many waves or many data points the calculation of the exact critical value can be very lengthy. All the results are saved in the wave W\_KWTestResults in the current data folder and are optionally displayed in a table (/T). The wave contains the following information:

$H_0$  for the Kruskal-Wallis test is that all input waves are the same. If the test fails and the input consisted of more than two waves, there is no indication for possible agreement between some of the waves. See **StatsNPMCTest** for further analysis.

V\_flag will be set to -1 for any error and to zero otherwise.

## StatsLinearCorrelationTest

---

Row	Data
0	Number of groups
1	Number of valid data points (excludes NaNs)
2	Alpha
3	Kruskal-Wallis Statistic H
4	Chi-squared approximation for the critical value Hc
5	Chi-squared approximation for the P value
6	Wallace approximation for the critical value Hc
7	Wallace approximation for the P value
8	Exact P value (requires /E)

## StatsLinearCorrelationTest

### StatsLinearCorrelationTest [flags] waveA, waveB

The StatsLinearCorrelationTest operation performs correlation tests on *waveA* and *waveB*, which must be real valued numeric waves and must have the same number of points. Output is to the W\_StatsLinearCorrelationTest wave in the current data folder or optionally to a table.

### Flags

- /ALPH = *val*      Sets the significance level (default *val*=0.05).
- /CI                    computes confidence intervals for the correlation coefficient.
- /Q                    No results printed in the history area.
- /RHO=*rhoValue*    Tests hypothesis that the correlation has a nonzero value  $|r| \leq 1$ .
- /T=*k*                Displays results in a table. *k* specifies the table behavior when it is closed.  
*k*=0:      Normal with dialog (default).  
*k*=1:      Kills with no dialog.  
*k*=2:      Disables killing.
- /Z                    Ignores errors.

### Details

The linear correlation tests start by computing the linear correlation coefficient for the *n* elements of both waves:

$$r = \frac{\sum_{i=1}^n X_i Y_i - \frac{1}{n} \sum_{i=1}^n X_i \sum_{i=1}^n Y_i}{\sqrt{\left( \sum_{i=1}^n X_i^2 - \frac{1}{n} \left( \sum_{i=1}^n X_i \right)^2 \right) \left( \sum_{i=1}^n Y_i^2 - \frac{1}{n} \left( \sum_{i=1}^n Y_i \right)^2 \right)}}$$

Next it computes the standard error of the correlation coefficient  $sr = \sqrt{\frac{1-r^2}{n-2}}$

The basic test is for hypothesis  $H_0$ : the correlation coefficient is zero, in which case  $t$  and  $F$  statistics are applicable. It computes  $t=r/sr$ ,  $F=(1+|r|)/(1-|r|)$ , and then the critical values for one and two tailed hypotheses (designated by  $t_{c1}$ ,  $t_{c2}$ ,  $F_{c1}$ , and  $F_{c2}$  respectively). Critical value for  $r$  are computed using

$$rc_i = \sqrt{\frac{t_c^2}{t_c^2 + n}}$$

where  $i$  takes the values 1 or 2 for one and two tailed hypotheses. Finally, it computes the power of the test at the alpha significance level for both one and two tails (Power1 and Power2).

If you use /RHO it uses the Fisher transformation to compute  $FisherZ = \frac{1}{2} \ln\left(\frac{1+r}{1-r}\right)$  and  $zeta = \frac{1}{2} \ln\left(\frac{1+\rho}{1-\rho}\right)$

the standard error approximation  $\sigma Z = \sqrt{1/(n-3)}$  and  $Z_{statistic} = (FisherZ - zeta) / \sigma Z$  and the critical values from the normal distribution  $Z_{ci}$ .

The confidence intervals are calculated differently depending on the hypothesis for the value of the correlation coefficient. If /RHO is not used the confidence intervals are computed using the critical value  $F_{c2}$ , otherwise they are computed using the critical  $Z_{c2}$  and  $\sigma Z$ .

Chapter III-12, **Statistics** for a function and operation overview; **StatsCircularCorrelationTest**, **StatsMultiCorrelationTest**, and **StatsRankCorrelationTest**.

## StatsLinearRegression

**StatsLinearRegression** [*flags*] [*wave0*, *wave1*,...]

The StatsLinearRegression operation performs regression analysis on the input wave(s). Output is to the W\_StatsLinearRegression wave in the current data folder or optionally to a table. Additionally, the M\_DunnettMCElevations, M\_TukeyMCSlopes, and M\_TukeyMCElevations waves may be created as specified.

### Flags

- /ALPH = *val* Sets the significance level (default *val*=0.05).
- /B=*beta0* Tests the hypothesis that the slope  $b = \text{beta0}$  (default is 0). The results are expressed by the t-statistic, which can be compared with the  $t_c$  value for the two-tailed test. Get the critical value for a one-tailed test using `StatsStudentCDF(1-alpha, N-2)`. It does not work with /MYVW.
- /BCIW Computes two confidence interval waves for the high side and the low side of the confidence interval. The new waves are named with `_CH` and `_CL` suffixes respectively appended to the Y wave name and are created in the current data folder. For multiple runs a numeric suffix will also be appended to the names.
- /BPIW[=*mAdditional*] Computes prediction interval waves for the high side and the low side of the confidence interval on a single additional measurement (default). Use *mAdditional* to specify additional measurements. The new waves are named with `_PH` and `_PL` suffixes respectively appended to the Y wave name and are created in the current data folder. For multiple runs a numeric suffix will also be appended to the names.
- /DET=*controlIndex* Performs Dunnett's multicomparison test for the elevations. The test requires more than two Y waves for regression, the test for the slopes should not reject the equal slope hypothesis, and the test for the elevations should reject the equal elevation hypothesis. *controlIndex* is the zero-based index of the Y wave representing the control (X waves do not count in the index specification). The test compares the elevation of every Y wave with the specified control.

## StatsLinearRegression

---

Output is to the M\_DunnettMCElevations wave in the current data folder or optionally to a table. For every Y wave and control Y wave combination, the results include SE, q, q' (shown as qp), and the conclusion with 1 to accept the hypothesis of equal elevations or 0 to reject it. Use /TAIL to determine the critical value and the sense of the test. If you use /TUK you will also get the Tukey test for the set of elevations.

/MYVW={*xWave*, *yWave*}

Specifies that the input consists of multiple Y values for each X value. It ignores all other inputs and the results are appropriate only for multiple Y values at each X point. *yWave* is a 2D wave of values arranged in columns. Use NaNs for padding where rows do not have the same number of entries as others. It will use the X scaling of *yWave* when *xWave* is null, /MYVW={\*, *yWave*}.

It first tests the hypothesis ( $H_0$ ) that the population regression is linear in an analysis of variance calculation. It generates results 1-7 (see Details) as well as: Among Groups SS, Among Groups DF, Within Groups SS, Within Groups DF, Deviations from Linearity SS, Deviations from Linearity DF, F statistic defined by the ratio of Deviation from Linearity MS to Within Groups MS, and the critical value  $F_c$ .

Next, it tests the hypothesis that the slope  $\beta=0$ . If the original  $H_0$  was accepted, the new F statistic= $\text{regressionMS}/\text{residualMS}$ . Otherwise the with the critical  $F=\text{regressionMS}/\text{WithinGroupsMS}$  with a corresponding critical value. Finally, it reports the values of the coefficient of determination  $r^2$  and the standard error of the estimate  $S_{YX}$ .

/PAIR

Specifies that the input waves are XY pairs, where each pair must be an X wave followed by a Y wave.

/Q

No results printed in the history area.

/RTO

Reflects the regression through the origin.

/T=*k*

Displays results in a table. *k* specifies the table behavior when it is closed.

*k*=0: Normal with dialog (default).

*k*=1: Kills with no dialog.

*k*=2: Disables killing.

/TAIL=*tCode*

Sets the sense of the test when applying Dunnett's test (see /DET). *tCode* is 1 or 2 for a one-tail critical value and 4 for a two-tail critical value.

/TUK

Performs a Tukey-type test on multiple regressions on two or more Y waves. There are two possible Tukey-type tests: The first is performed if the hypothesis of equal slopes is rejected. It compares all combinations of two Y waves to identify if some of the waves have equal slopes. Output is to the M\_TukeyMCSlopes wave in the current data folder or optionally to a table. For every Y wave pair, the results include the difference between slopes (absolute value), q, the critical value  $q_c$ , and the conclusion set to 1 for accepting the equality of the pair of slopes or 0 for rejecting the hypothesis.

The second Tukey-type test is performed if all the slopes are the same but the elevations are not. The test (see /DET) compares all possible pairs of elevations to determine which satisfy the hypothesis of equality. Output is to the M\_TukeyMCElevations wave in the current data folder.

/WSTR=*waveListString*

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.

/Z

Ignores errors.

### Details

Inputs may consist of Y waves or XY wave pairs. If X data are not used, the X values are inferred from the Y wave scaling. For multiple waves where only some have pairs, use the /PAIR flag and enter \* in each place where the X values should be computed.

For each input StatsLinearRegression calculates:

1. Least squares regression line  $y=a+b*x$ .
2. Mean value of X:  $\bar{x}$ .
3. Mean value of Y:  $\bar{y}$ .
4. Sum of the squares  $(x_i-\bar{x})^2$ .
5. Sum of the squares  $(y_i-\bar{y})^2$ .

6. Sum of the product ( $x_i y_i - \bar{x} \bar{y}$ ).
7. Standard error of the estimate  $S_{YX}$ .
8. F statistic for the hypothesis  $\beta = 0$ .
9. Critical F value  $F_c$ .
10. Coefficient of determination  $r^2$ .
11. Standard error of the regression coefficient  $S_b$ .
12. t-statistic for the hypothesis  $\beta = \beta_0$ , NaN if /B is not specified.
13. Critical value  $t_c$  for the t-statistic above (used to calculate L1 and L2).
14. Lower confidence interval boundary (L1) for the regression coefficient.
15. Upper confidence interval boundary (L2) for the regression coefficient.

For two Y waves with the same slope, it computes a common slope (bc) and then tests the equality of the elevations (a). In both cases it computes a t-statistic and compares it with a critical value. If the elevations are also the same then it computes the common elevation (ac) and the pooled means of X and Y in (xp) and (yp).

For more than two Y waves it computes:

$$A_c = \sum_{j=1}^W A_j; \quad A_j = \sum x_i^2 = \sum_{i=0}^{n_j-1} X_i^2 - \frac{1}{n_j} \left( \sum_{i=0}^{n_j-1} X_i \right)^2$$

$$B_c = \sum_{j=1}^W B_j; \quad B_j = \sum xy = \sum_{i=0}^{n_j-1} XY - \frac{1}{n_j} \left( \sum_{i=0}^{n_j-1} X_i \right) \left( \sum_{i=0}^{n_j-1} Y_i \right)$$

$$C_c = \sum_{j=1}^W C_j; \quad C_j = \sum y^2 = \sum_{i=0}^{n_j-1} Y_i^2 - \frac{1}{n_j} \left( \sum_{i=0}^{n_j-1} Y_i \right)^2$$

$$SSp = \sum_{j=1}^W C_j - \frac{B_c^2}{A_c} \quad SSr = C_c - \frac{B_c^2}{A_c} \quad SSr = \sum_{j=1}^W \sum_{i=0}^{n_j-1} Y_i^2 - \frac{1}{N} \left( \sum_{j=1}^W \sum_{i=0}^{n_j-1} Y_i \right)^2 - \frac{\left( \sum_{j=1}^W \sum_{i=0}^{n_j-1} X_i Y_i - \frac{1}{N} \left( \sum_{j=1}^W \sum_{i=0}^{n_j-1} X_i \right) \left( \sum_{j=1}^W \sum_{i=0}^{n_j-1} Y_i \right) \right)^2}{\sum_{j=1}^W \sum_{i=0}^{n_j-1} X_i^2 - \frac{1}{N} \left( \sum_{j=1}^W \sum_{i=0}^{n_j-1} X_i \right)^2}$$

$$DFp = \sum_{j=1}^W (n_j - 2) \quad DFr = \sum_{j=1}^W n_j - 2$$

where  $W$  is the number of Y-waves and  $N = \sum_{j=1}^W n_j$  is the total number of data points in all Y-waves.

The test statistic  $F$  for equality of slopes is given by:  $F = \left( \frac{SSr - SSp}{numWaves - 1} \right) / \frac{SSp}{DFp}$

$F_c$  is the corresponding critical value.

Output is to the W\_LinearRegressionMC wave in the current data folder.

V\_flag will be set to -1 for any error and to zero otherwise.

## StatsLogNormalPDF

**StatsLogNormalPDF(x, σ [, θ, μ])**

The StatsLogNormalPDF function returns the lognormal probability distribution function

$$f(x,\sigma,\theta,\mu) = \frac{1}{\sigma\sqrt{2\pi}} \frac{1}{x-\theta} \exp\left[-\left[\ln\left(\frac{x-\theta}{\mu}\right)\right]^2 / 2\sigma^2\right]$$

for  $x \geq \theta$  and  $\sigma, \mu > 0$ , where  $\theta$  is the location parameter,  $\mu$  is the scale parameter and,  $\sigma$  is the shape parameter. The standard lognormal distribution is for  $\theta=0$  and  $\mu=1$ , which are the optional parameter defaults.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsLogNormalCDF** and **StatsInvLogNormalCDF** functions.

## StatsMaxwellCDF

**StatsMaxwellCDF(x, k)**

The StatsMaxwellCDF function returns the Maxwell cumulative distribution function

$$F(x;k) = \text{gammp}\left(\frac{3}{2}, \frac{kx^2}{2}\right), \quad x > 0$$

where **gammp** is the regularized incomplete gamma function.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsMaxwellPDF** and **StatsInvMaxwellCDF** functions.

**StatsMaxwellPDF****StatsMaxwellPDF(x, k)**

The StatsMaxwellPDF function returns Maxwell's probability distribution function

$$f(x,k) = \sqrt{\frac{2}{\pi}} k^{3/2} x^2 \exp\left(-\frac{kx^2}{2}\right), \quad x \geq 0$$

The Maxwell distribution describes, for example, the speed distribution of molecules in an ideal gas.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsMaxwellCDF** and **StatsInvMaxwellCDF** functions.

**StatsMedian****StatsMedian(waveName)**

The StatsMedian function returns the median value of a numeric wave *waveName*, which must not contain NaNs.

**Example**

```
Make/N=5 sample1={1,2,3,4,5}
Print StatsMedian(sample1)
3
Make/N=6 sample2={1,2,3,4,5,6}
Print StatsMedian(sample2)
3.5
```

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **WaveStats** and **StatsQuantiles**.

**StatsMooreCDF****StatsMooreCDF(x, N)**

The StatsMooreCDF function returns the cumulative distribution function for Moore's  $R^*$ , which is used in a nonparametric version of the Rayleigh test for uniform distribution around the circle. It supports the range  $3 \leq N \leq 120$  and does not change appreciably for  $N > 120$ .

The distribution is computed from polynomial approximations derived from simulations and should be accurate to approximately three significant digits.

**References**

Moore, B.R., A modification of the Rayleigh test for vector data, *Biometrika*, 67, 175-180, 1980.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsCircularMeans** function.

**StatsMultiCorrelationTest****StatsMultiCorrelationTest [flags] corrWave, sizeWave**

The StatsMultiCorrelationTest operation performs various tests on multiple correlation coefficients. Inputs are two 1D waves: *corrWave*, containing correlation coefficients, and *sizeWave*, containing the size (number of elements) of the corresponding samples. Although you can do all the tests at the same time, it rarely makes sense to do so.

**Flags**

/ALPH = *val*      Sets the significance level (default *val*=0.05).

/CON={*controlRow,tails*}

Performs a multiple comparison test using the *controlRow* element of *corrWave* as a control. It is one- or two-tailed test according to the *tails* parameter. Output is to the *M\_ControlCorrTestResults* wave in the current data folder.

## StatsMultiCorrelationTest

`/CONT=cWave` Performs a multiple contrasts test on the correlation coefficients. The contrasts wave, `cWave`, contains the contrast factor,  $c_i$ , entry for each of the  $n$  correlation coefficients  $r_i$  in `corrWave`, and satisfying the condition that the sum of the entries in `cWave` is zero.  $H_0$  corresponds to

$$\sum_{i=0}^{n-1} c_i r_i = 0$$

The test statistic  $S$  is

$$S = \left| \sum_{i=0}^{n-1} c_i z_i \right| / \sqrt{\frac{c_i^2}{n_i - 3}}$$

where  $z_i$  is the Fisher  $z$  transform of the correlation coefficient  $r_i$ :

$$z_i = \frac{1}{2} \ln \left( \frac{1+r_i}{1-r_i} \right)$$

It produces the SE value, the contrast statistic  $S$ , and the critical value, which are labeled `ContrastSE`, `ContrastS`, and `Contrast_Critical`, respectively, in the `W_StatsMultiCorrelationTest` wave.

`/Q` No results printed in the history area.

`/T=k` Displays results in a table.  $k$  specifies the table behavior when it is closed.

$k=0$ : Normal with dialog (default).

$k=1$ : Kills with no dialog.

$k=2$ : Disables killing.

`/TUK` Performs a Tukey-type multi comparison testing between the correlation coefficients by comparing every possible combination of pairs of correlation coefficients, computing the difference in their  $z$ -transforms, the SE, and the  $q$  statistic:

$$q = \frac{|z_j - z_i|}{\sqrt{2 \left( \frac{1}{n_i - 3} + \frac{1}{n_j - 3} \right)}}$$

The critical value is computed from the  $q$  CDF (`StatsInvQCDF`) with degrees of freedom `numWaves` and infinity. Output is to the `M_TukeyCorrTestResults` wave in the current data folder or optionally to a table.

`/Z` Ignores errors. `V_wgl` will be set to -1 for any error and to zero otherwise.

### Details

Without any flags, `StatsMultiCorrelationTest` computes  $\chi^2$  for the correlation coefficients and compares it with the critical value.

$$\chi^2 = \sum_{i=0}^{n-1} z_i^2 (n_i - 3) - \frac{\left( \sum_{i=0}^{n-1} z_i (n_i - 3) \right)^2}{\sum_{i=0}^{n-1} (n_i - 3)}$$

where  $z_i$  is the Fisher's  $z$  transform of the correlation coefficients and  $n_i$  is the corresponding sample size. It computes the common correlation coefficient `rw` and its transform `zw`.

$$z_w = \frac{\sum_{i=0}^{n-1} z_i (n_i - 3)}{\sum_{i=0}^{n-1} (n_i - 3)}$$

These values are calculated even when not appropriate, such as when  $\chi^2$  exceeds the critical value and  $H_0$  (all samples came from populations of identical correlation coefficients) is rejected.

The operation also computes ChiSquaredP (due to S.R. Paul), a different variant of  $\chi^2$  that is corrected for bias and should be compared with the same critical value. Output is to the W\_StatsMultiCorrelationTest wave in the current data folder or optionally to a table.

## StatsNBinomialCDF

### **StatsNBinomialCDF(x, k, p)**

The StatsNBinomialCDF function returns the negative binomial cumulative distribution function

$F(x, k, p) = \text{Betain}(k, x+1, p)$  where **betain** is the regularized incomplete beta function.

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNBinomialPDF** and **StatsInvNBinomialCDF** functions.

## StatsNBinomialPDF

### **StatsNBinomialPDF(x, k, p)**

The StatsNBinomialPDF function returns the negative binomial probability distribution function

$$f(x, k, p) = \binom{x+k-1}{k-1} p^k (1-p)^x, \quad x = 0, 1, 2, \dots$$

where  $\binom{a}{b}$  is the **binomial** function.

The binomial distribution expresses the probability of the  $k$ th success in the  $x+k$  trial for two mutually exclusive results (success and failure) and  $p$  the probability of success in a single trial.

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNBinomialCDF** and **StatsInvNBinomialCDF** functions.

## StatsNCChiCDF

### **StatsNCChiCDF(x, n, d)**

The StatsNCChiCDF function returns the noncentral chi-squared cumulative distribution function

$$F(x, n, d) = \sum_{i=0}^{\infty} \exp(-d/2) \frac{(d/2)^i}{i!} F_c(x, n + 2i)$$

where  $n > 0$  corresponds to degrees of freedom,  $d \geq 0$  is the noncentrality parameter, and  $F_c$  is the central chi-squared distribution.

Chapter III-12, **Statistics** for a function and operation overview; the **StatsChiCDF**, **StatsNCChiPDF**, and **StatsChiPDF** functions.

## StatsNCChiPDF

### **StatsNCChiPDF(x, n, d)**

The StatsNCChiPDF function returns the noncentral chi-squared probability distribution function

$$f(x, n, d) = \frac{\sqrt{d} \exp\left(-\frac{x+d}{2}\right) x^{(n-1)/2}}{2(dx)^{n/4}} I_{n/2-1}(\sqrt{dx})$$

where  $n > 0$  is the degrees of freedom,  $d \geq 0$  is the noncentrality parameter, and  $I_k(x)$  is the modified Bessel function of the first kind, **bessI**.

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNCChiCDF**, **StatsInvNCChiCDF**, **StatsChiCDF**, and **StatsChiPDF** functions.

## StatsNCFCDF

### StatsNCFCDF(*x*, *n1*, *n2*, *d*)

The StatsNCFCDF function returns the cumulative distribution function of the noncentral F distribution. *n1* and *n2* are the shape parameters and *d* is the noncentrality measure. There is no closed form expression for the distribution.

#### References

Evans, M., N. Hastings, and B. Peacock, *Statistical Distributions*, 3rd ed., Wiley, New York, 2000.

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNCFPDF** and **StatsInvNCFCDF** functions.

## StatsNCFPDF

### StatsNCFPDF(*x*, *n1*, *n2*, *d*)

The StatsNCFPDF function returns the probability distribution function of the noncentral F distribution

$$f(x; n_1, n_2, d) = \frac{\exp(-d/2)}{B\left(\frac{n_1}{2}, \frac{n_2}{2}\right)} x^{n_1/2-1} (xn_1 + n_2)^{-(n_1+n_2)/2} n_1^{n_1/2} n_2^{n_2/2} {}_1F_1\left(\frac{n_1+n_2}{2}, \frac{n_1}{2}, \frac{xdn_1}{2(xn_1+n_2)}\right)$$

where  $B()$  is the **beta** function and  ${}_1F_1()$  is the hypergeometric function **hyperG1F1**.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsStudentPDF**, **StatsStudentCDF**, and **StatsNCTCDF** functions.

**StatsNormalCDF****StatsNormalCDF(x, m, s)**

The StatsNormalCDF function returns the normal cumulative distribution function

$$F(x, \mu, \sigma) = \frac{1}{2} + \frac{1}{2} \operatorname{erf}\left(\frac{x - \mu}{\sigma\sqrt{2}}\right) \text{ where } \operatorname{erf} \text{ is the error function.}$$

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNormalPDF** and **StatsInvNormalCDF** functions.

**StatsNormalPDF****StatsNormalPDF(x, m, s)**

The StatsNormalPDF function returns the normal probability distribution function

$$f(x, \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x - \mu)^2}{2\sigma^2}\right)$$

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNormalCDF** and **StatsInvNormalCDF** functions.

**StatsNPMCTest****StatsNPMCTest [flags] [wave1, wave2, ... wave100]**

The StatsNPMCTest operation performs a number of nonparametric multiple comparison tests. Output waves are saved in the current data folder according to the test(s) performed. Some tests are only appropriate when you have the same number of samples in all groups. StatsNPMCTest usually follows **StatsANOVA1Test** or **StatsKWTest**.

**Flags**

/ALPH = *val* Sets the significance level (default *val*=0.05).

/CIDX=*controlIndex* Performs nonparametric multiple comparisons on a control group specified by the zero-based *controlIndex* wave in the input list. Output is to the M\_NPCCResults wave in the current data folder or optionally to a table. The output column contents are: the first contains the difference between the rank sums of the control and each of the other waves; the second contains the standard error (SE); the third contains the statistic *q*, defined as the ratio of the difference in rank sums to SE; the fourth contains the critical value which also depends on the tails specification (see /TAIL); and the fifth contains the conclusion with 0 to reject  $H_0$  and 1 to accept it. One version of this test applies when all inputs contain the same number of samples. When that is not the case, it uses the Dunn-Hollander-Wolfe approach to compute an appropriate SE and to handle possible ties.

/CONW=*cWave* Performs a nonparametric multiple contrasts tests. *cWave* has one point for each input wave. The *cWave* value is 1 to include the corresponding (zero based) input wave in the first group, 2 to include the wave in the second group, or zero to exclude the wave.

The contrast is defined as the difference between the normalized sum of the ranks of the first group and that of the second group. If  $cWave=\{0,1,1,1,2\}$ , then the contrast is computed as

$$\text{contrast: } \frac{1}{3}[R_{c1}+R_{c2}+R_{c3}]-R_{c4}$$

where  $R_{ni}$  is the normalized rank sum of the samples from the corresponding input wave. Note the significance of allowing zeros in the contrast wave because the actual ranking is performed on the pool of all the samples.

Output is to the M\_NPMConResults wave in the current data folder or optionally to a table. The output column contents are: the first is the contrast value; the second is the standard error (SE); the third is the statistic S, which is the ratio of the absolute value of the contrast to SE; the fourth is the critical value (from  $\chi^2$  the approximation); and the fifth is the conclusion with 0 to reject  $H_0$  and 1 indicating acceptance.

This test supports input waves with different number of samples and can also handle tied ranks. Note that the contrast wave used here is structured differently than for **StatsMultiCorrelationTest**.

/DHW	Performs the Dunn-Holland-Wolfe test, which supports unequal number of samples and accounts for ties in the rank sums. Output is to the M_NPMCDHWResults wave in the current data folder or optionally to a table. The output column contents are: the first contains the difference between the means of the rank sums (rank sums divided by the number of samples in the group), the second contains the standard error (SE), the third contains the DHW statistic Q, the fourth contains the critical value, and the fifth contains the conclusion (0 to reject $H_0$ and 1 to accept).
/Q	No results printed in the history area.
/SWN	Creates a text wave, T_NPCCRResultsDescriptors, containing wave names corresponding to each row of the comparison table (Save Wave Names). Use /T to append the text wave to the last column.
/T=k	Displays results in a table. $k$ specifies the table behavior when it is closed. $k=0$ : Normal with dialog (default). $k=1$ : Kills with no dialog. $k=2$ : Disables killing. The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results.
/TAIL=tc	Specifies $H_0$ with /CIDX. $tc=1$ : One tailed test ( $\mu_c \leq \mu_a$ ). $tc=2$ : One tailed test ( $\mu_c \geq \mu_a$ ). $tc=4$ : Default; two tailed test ( $\mu_c = \mu_a$ ). Code combinations are not allowed.
/SNK	Performs a nonparametric variation on the Student-Newman-Keuls test where the standard error SE is a function of $p$ (the rank difference). This test requires equal numbers of samples in all groups; use /DHW for unequal sizes. Output is to the M_NPMCSNKResults wave in the current data folder. The output column contents are: the first contains the difference between rank sums, the second contains the standard error (SE), the third contains the $p$ value (rank difference), the fourth the statistic, the fifth contains the critical value, and the sixth contains the conclusion (0 to reject $H_0$ and 1 to accept). This test is more sensitive to differences than the Tukey test (/TUK).
/TUK	Perform a Tukey-type (Nemenyi) multiple comparison test using the difference between the rank sums. This is the default that is performed if you do not specify any of the test flags. This test requires equal numbers of points in all waves; use /DHW for unequal sizes. Output is to the M_NPMCTukeyResults wave in the current data folder. The output column contents are: the first contains the difference between the rank sums, the second contains the SE values, the third contains the statistic $q$ , the fourth contains the critical value for this specific alpha and the number of groups; and the last contains a

conclusion flag with 0 indicating a rejection of  $H_0$  and 1 indicating acceptance.  $H_0$  postulates that the paired means are the same.

/WSTR=*waveListString*

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.

/Z

Ignores errors.

### Details

Inputs to StatsNPMCTest are two or more 1D numerical waves (one wave for each group of samples) containing two or more valid entries. The waves must have the same number of points for the use /SNK and /TUK tests, otherwise, for waves of differing lengths you must use the Dunn-Hollander-Wolfe test (/DHW).

V\_flag will be set to zero for no execution errors. Individual tests may fail if, for example, there are different number of samples in the input waves for a test that requires an equal number of points. StatsNPMCTest skips failed tests and V\_flag will be a binary combination identifying the failed test(s):

V\_flag & 1            Tukey method failed (/TUK).

V\_flag & 2            Student-Newman-Keuls failed (/SNK).

V\_flag will be set to -1 for any other errors.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsANOVA1Test** and **StatsKWTest**.

For multiple comparisons in parametric tests see: **StatsDunnnettTest** and **StatsScheffeTest**.

## StatsNPNominalSRTest

**StatsNPNominalSRTest** [ *flags* ] [ *srcWave* ]

The StatsNPNominalSRTest operation performs a nonparametric serial randomness test for nominal data consisting of two types. The null hypothesis is that the data are randomly distributed. Output is to the W\_StatsNPSRTest wave in the current data folder.

### Flags

/ALPH = *val*            Sets the significance level (default *val*=0.05).

/Q                        No results printed in the history area.

/P={*m,n,u*}            Provides a summary of the data instead of providing the nominal series. *m* is the number of elements of the first type, *n* is the number of elements of the second type, and *u* is the number of runs or contiguous sequences of each type. Do not use *srcWave* with /P.

/T=*k*                    Displays results in a table. *k* specifies the table behavior when it is closed.

*k*=0:    Normal with dialog (default).

*k*=1:    Kills with no dialog.

*k*=2:    Disables killing.

/Z

Ignores errors.

### Details

The input wave to StatsNPNominalSRTest is specified with *srcWave* or /P. The wave must contain exactly two values. If *srcWave* is a text wave, then each type can be designated by a letter or by a short string (less than 200 characters). If *srcWave* is numeric, you should avoid the usual floating point waves, which can give rise to internal representations of more than two distinct values. Output to W\_StatsNPSRTest includes the total number of points (*N*), the number of occurrences (*m*) of the first variable, the number of occurrences (*n*) of the second variable, and the number of runs (*u*). When both *m* and *n* are less than 300, it computes the P value (probability  $P(u' < u)$ ) and the critical values using the Swed and Eisenhart algorithm. When *m* or *n* are larger than 300, it computes the mean and standard deviation of an equivalent normal distribution with the corresponding critical value.

### References

## StatsParetoCDF

---

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsSRTTest**.

## StatsParetoCDF

**StatsParetoCDF(x, a, c)**

The StatsParetoCDF function returns the Pareto cumulative distribution function  $F(x;a,c) = 1 - \left(\frac{a}{x}\right)^c$

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsParetoPDF** and **StatsInvParetoCDF** functions.

## StatsParetoPDF

**StatsParetoPDF(x, a, c)**

The StatsParetoPDF function returns the Pareto probability distribution function

$$f(x;a,c) = \frac{c}{x} \left(\frac{a}{x}\right)^{c-1}, \quad \begin{array}{l} a,c > 0 \\ x \geq a \end{array}$$

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsParetoCDF** and **StatsInvParetoCDF** functions.

## StatsPermute

**StatsPermute(waveA, waveB, dir)**

The StatsPermute function permutes elements in *waveA* based on the lexicographic order of *waveB* and the direction *dir*. It returns 1 if a permutation is possible and returns 0 otherwise. Use *dir*=1 for the next permutation and *dir*=-1 for a previous permutation.

### Details

Both *waveA* and *waveB* must be numeric. The lexicographic order of elements in the index wave is set so that permutations start with the index wave *waveB* in ascending order and end in descending order. Elements of *waveA* are permuted in place according to the order of the indices in *waveB* which are clipped (after permutation) to the valid range of entries in *waveA*. *waveB* is also permuted in place in order to allow you to obtain sequential permutations. If *waveA* consists of real numbers you can permute them using the lexicographic value of the entries directly. To do so pass "\$" for *waveB*. Whenever it returns 0, neither *waveA* and *waveB* are changed.

### Examples

```
Function allPermutations(num)
  Variable num
  Variable i,nf=factorial(num)
  Make/O/N=(num) wave0=p+1,waveA,waveB=p
  Print wave0
  for(i=0;i<nf;i+=1)
    waveA=wave0
    if(statsPermute(waveA,waveB,1)==0)
      break
    endif
    print waveA
  endfor
end
```

Executing allPermutations(3) prints:

```
wave0[0]= {1,2,3}
waveA[0]= {1,3,2}
waveA[0]= {2,1,3}
waveA[0]= {2,3,1}
waveA[0]= {3,1,2}
waveA[0]= {3,2,1}
```

### See Also

Chapter III-12, **Statistics** for a function and operation overview.

## StatsPoissonCDF

### **StatsPoissonCDF(x, λ)**

The StatsPoissonCDF function returns the Poisson cumulative distribution function

$$F(x, \lambda) = \sum_{i=0}^x \frac{\exp(-\lambda)\lambda^i}{i!}, \quad x = 0, 1, 2, \dots$$

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsPoissonPDF** and **StatsInvPoissonCDF** functions.

## StatsPoissonPDF

### **StatsPoissonPDF(x, λ)**

The StatsPoissonPDF function returns the Poisson probability distribution function

$$f(x, \lambda) = \frac{\exp(-\lambda)\lambda^x}{x!}, \quad x = 0, 1, 2, \dots$$

where  $\lambda$  is the shape parameter.

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsPoissonCDF** and **StatsInvPoissonCDF** functions.

## StatsPowerCDF

### **StatsPowerCDF(x, b, c)**

The StatsPowerCDF function returns the Power Function cumulative distribution function

$$F(x; b, c) = \left(\frac{x}{b}\right)^c \text{ where the scale parameter } b \text{ and the shape parameter } c \text{ satisfy } b, c > 0 \text{ and } b \geq x \geq 0.$$

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsPowerPDF** and **StatsInvPowerCDF** functions.

## StatsPowerNoise

### **StatsPowerNoise(b, c)**

The StatsPowerNoise function returns a pseudorandom value from the power distribution function with probability distribution:

$$f(x, b, c) = \frac{c}{x} \left(\frac{x}{b}\right)^c$$

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **SetRandomSeed**, **StatsPowerPDF**, **StatsInvPowerCDF**, and **StatsInvPowerCDF** functions.

## StatsPowerPDF

### **StatsPowerPDF(x, b, c)**

The StatsPowerPDF function returns the Power Function probability distribution function

$$F(x; b, c) = \frac{c}{x} \left(\frac{x}{b}\right)^c \text{ where the scale parameter } b \text{ and the shape parameter } c \text{ satisfy } b, c > 0 \text{ and } b \geq x \geq 0.$$

## StatsQCDF

---

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsPowerCDF** and **StatsInvPowerCDF** functions.

## StatsQCDF

### **StatsQCDF**(*q*, *r*, *c*, *df*)

The **StatsQCDF** function returns the value of the Q cumulative distribution function for *r* the number of groups, *c* the number of treatments, and *df* the error degrees of freedom ( $f=rc(n-1)$  with sample size *n*).

### Details

The Q distribution is the maximum of several Studentized range statistics. For a simple Tukey test, use  $r=1$ .

## StatsQuantiles

### **StatsQuantiles** [*flags*] *srcWave*

The **StatsQuantiles** operation computes quantiles and elementary univariate statistics for a set of data in *srcWave*.

### Flags

/ALL	Invokes all flags except /Q, /QM, and /Z.
/BOX	Computes parameters necessary to construct a box plot.
/iNaN	Ignores NaNs, which are sorted to the end of the array by default.
/IW	Creates an index wave W_QuantilesIndex. W_QuantilesIndex[ <i>i</i> ] corresponds to the position of <i>srcWave</i> [ <i>i</i> ] when sorted from minimum to maximum.
/Q	No information printed in the history area.
/QM= <i>qMethod</i>	Specifies the method for computing quartiles. <i>qMethod</i> has one of these values: 0: Tukey (default). 1: Minitab. 2: Moore and McCabe. 3: Mendenhall and Sincich. See Details for more information.
/QW	Creates a single precision wave W_QuantileValues containing the quantile value corresponding to each entry in <i>srcWave</i> .
/STBL	Uses a stable sort, which may require significant computation time for multiple entries with the same value.
/TM	Computes the tri-mean: $0.25*(V\_Q25+2*median+V\_Q75)$ .
/TRIM= <i>tVal</i>	Computes the trimmed mean which is the mean value of the entries between the quantiles <i>tVal</i> (in %) and $100-tVal$ . By default <i>tVal</i> =25 and the trimmed mean corresponds to the midmean.
/Z	Ignores any errors.

### Details

**StatsQuantiles** produces quick five-number summaries or more detailed results for univariate data. Values are returned in the wave W\_StatsQuantiles and in the variables:

V_min	Minimum value.
V_max	Maximum value.
V_Median	Median value.
V_Q25	Lower quartile.
V_Q75	Upper quartile.

V\_IQR Inter-quartile range V\_Q75-VQ25, which is also known as the H-spread.

Entries in the wave W\_StatsQuantiles depend on your choice of flags. Each row has a row label explicitly defining its value. If you use the /ALL flag, W\_StatsQuantiles will contain the following row labels:

minValue	lowerInnerFence
maxValue	lowerOuterFence
Median	upperInnerFence
Q25	upperOuterFence
Q75	triMean
IQR	trimmedMean

Otherwise, W\_StatsQuantiles will contain the first five entries and any additionally requested value. You should always access values using the dimension labels (see **Dimension Labels** on page II-93).

There is frequently some confusion in comparing statistical results computed by different programs because each may use a different definition of quartiles. You can specify the method of computing the quartiles as you prefer with the /QM flag. If you neglect to choose a method, StatsQuantiles uses Tukey's method, which computes quartiles (also called hinges) as the lower and upper median values between the median of the data and the edges of the array. The Moore and McCabe method is similar to Tukey's method except you do not include the median itself in computing the quartiles. Mendenhall and Sincich compute the quartiles using  $1/4$  and  $3/4$  of  $(\text{numDataPoints}+1)$  and round to the nearest integer (if the fraction part is exactly 0.5 they round up for the lower quartile and down for the upper quartile). Minitab uses the same expressions but instead of rounding it uses linear interpolation.

StatsQuantiles uses a stable index sorting routine so that

```
IndexSort W_QuantilesIndex,srcWave
```

is a monotonically increasing wave.

## StatsRankCorrelationTest

**StatsRankCorrelationTest** [*flags*] *waveA*, *waveB*

The StatsRankCorrelationTest operation performs Spearman's rank correlation test on *waveA* and *waveB*, 1D waves containing the same number of points. Output is to the W\_StatsRankCorrelationTest wave in the current data folder.

### Flags

/ALPH = <i>val</i>	Sets the significance level (default <i>val</i> =0.05).
/Q	No results printed in the history area.
/T= <i>k</i>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing.
/Z	Ignores errors.

### Details

StatsRankCorrelationTest ranks *waveA* and *waveB* and then computes the sum of the squared differences of ranks for all rows. Ties are assigned an average rank and the corrected Spearman rank correlation coefficient is computed with ties. It reports the sum of the squared ranks (sumDi2), the sums of the ties

## StatsRayleighCDF

---

coefficients (sumTx and sumTy respectively), the Spearman rank correlation coefficient (in the range [-1,1]), and the critical value.  $H_0$  corresponds to zero correlation against the alternative of nonzero correlation. The critical value is usually lower than the one in published tables. When the first derivative of the CDF is discontinuous, tables tend to use a more conservative value by choosing the next transition of the CDF as the critical value. StatsRankCorrelationTest is not as powerful as **StatsLinearCorrelationTest**.

**StatsLinearCorrelationTest**, **StatsCircularCorrelationTest**, **StatsKendallTauTest**, **StatsSpearmanRhoCDF**, and **StatsInvSpearmanCDF**.

## StatsRayleighCDF

**StatsRayleighCDF(x [, s [, m]])**

The StatsRayleighCDF function returns the Rayleigh cumulative distribution function

$F(x, \sigma, \mu) = 1 - \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right)$  with defaults  $s=1$  and  $m=0$ . It returns NaN for  $s \leq 0$  and zero for  $x \leq m$ .

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRayleighPDF** and **StatsInvRayleighCdf** functions.

## StatsRayleighPDF

**StatsRayleighPDF(x [, s [, m]])**

The StatsRayleighPDF function returns the Rayleigh probability distribution function

$f(x, \sigma, \mu) = \frac{x-\mu}{\sigma^2} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right)$  with defaults  $s=1$  and  $m=0$ . It returns NaN for  $s \leq 0$  and zero for  $x \leq m$ .

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRayleighCDF** and **StatsInvRayleighCdf** functions.

## StatsRectangularCDF

**StatsRectangularCDF(x, a, b)**

The StatsRectangularCDF function returns the rectangular (uniform) cumulative distribution function

$$F(x, a, b) = \begin{cases} 0 & x \leq a \\ \frac{x-a}{b-a} & a \leq x \leq b \\ 1 & x \geq b \end{cases} \quad \text{where } a < b.$$

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRectangularPDF** and **StatsInvRectangularCDF** functions.

## StatsRectangularPDF

**StatsRectangularPDF(x, a, b)**

The StatsRectangularPDF function returns the rectangular (uniform) probability distribution function

$$f(x, a, b) = \begin{cases} \frac{1}{b-a} & a \leq x \leq b \\ 0 & \text{otherwise} \end{cases}$$

where  $a < b$ .

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRectangularCDF** and **StatsInvRectangularCDF** functions.

**StatsResample****StatsResample** [*flags*] *srcWave*

The StatsResample operation resamples *srcWave* by drawing (with replacement)  $N=numPoints$  values from *srcWave* and storing them in the wave *W\_Resampled*. You can iterate the process and compute various statistics on the data samples.

**Flags**

<i>/ITER=n</i>	Repeats the resampling for <i>n</i> iterations, which is useful only when combined with <i>/WS</i> or <i>/SQ</i> .
<i>/K</i>	Kills <i>W_Resampled</i> after passing it to <i>WaveStats</i> . When <i>/ITER</i> is used, <i>W_Resampled</i> is not saved.
<i>/N=numPoints</i>	Specifies the number of points sampled from <i>srcWave</i> .
<i>/Q</i>	No information printed in the history area.
<i>/SQ=m</i>	Uses <i>StatsQuantiles</i> to compute the data quartiles. The methods are: <i>m=0</i> : Tukey (default). <i>m=1</i> : Minitab. <i>m=2</i> : Moore and McCabe. <i>m=3</i> : Mendenhall and Sincich. See Details for information about how the results are stored. The default trim value is 25%.
<i>/WS=m</i>	Uses <i>WaveStats</i> operation to calculate data statistics. <i>m=0</i> : Creates a new wave containing the samples (default). <i>m=1</i> : Creates the new wave and passes it to <i>WaveStats/Q/M=1</i> . <i>m=1</i> : Creates the new wave and passes it to <i>WaveStats/Q/M=2</i> . See Details for information about how the results are stored.
<i>/Z</i>	Ignores any errors.

**Details**

StatsResample can perform Bootstrap Analysis, permutations tests, and Monte-Carlo simulations. It draws the specified number of data points (with replacement) from *srcWave* and places them in a destination wave *W\_Resampled*.

Specify */WS* or */SQ* to use the *WaveStats* or *StatsQuantiles* operations, respectively, to compute results directly from the data. StatsResample normally creates the wave *W\_Resampled* and, optionally, the *M\_WaveStats* and *W\_StatsQuantiles* waves. Both options also create various *V\_* variables. If you use more than one iteration, StatsResample creates instead the waves *M\_WaveStatsSamples* and *M\_StatsQuantilesSamples* for the results.

*M\_WaveStatsSamples* (with */WS*) contains a column for each iteration. Each column is equivalent to the contents of *M\_WaveStats* for that iteration. You can use the command

```
Edit M_WaveStatsSamples.ld
```

to display the results in a table using row labels, and, for example, to display a graph of the rms of the samples as a function of iteration number execute:

```
Display M_WaveStatsSamples[5][ ]
```

*M\_StatsQuantilesSamples* (with */SQ*) contains a column for each iteration. Each column consists of the contents of *W\_StatsQuantiles* for the corresponding data. Here again you can execute the command

```
Edit M_StatsQuantilesSamples.ld
```

to display the wave in a table using row labels. To display a graph of the median as a function of iteration execute:

```
Display M_statsQuantilesSamples[2][ ]
```

**Note:** Both *WaveStats* and *StatsQuantiles* create *V\_* variables. Some are used by both operations. These variables are valid only if you use either */SQ* or */WS*, but not both, and only if you are not using */ITER*.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **WaveStats** and **StatsQuantiles**.

**StatsRunsCDF**

**StatsRunsCDF**(*n*, *r*)

The StatsRunsCDF function returns the cumulative distribution function for the up and down runs distribution for total number of runs *r* in a random linear arrangement of *n* unequal elements. There is no closed form expression. It is computed numerically from the recursion of the probability density

$$f(r, n) = \frac{rf(r, n-1) + 2f(r-1, n-1) + (n-r)f(r-2, n-1)}{n} \text{ with the initial condition } f(1, n) = \frac{2}{n!}.$$

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsSRTTest** function.

**StatsScheffeTest**

**StatsScheffeTest** [*flags*] [*wave1*, *wave2*,... *wave100*]

The StatsScheffeTest operation performs Scheffe's test for the equality of the means. It supports two basic modes: the default tests all possible combinations of pairs of waves; the second tests a single combination where the precise form of  $H_0$  is determined by the coefficients of a contrast wave (see /CONT). Output is to the M\_ScheffeTestResults wave in the current data folder.

**Flags**

/ALPH=*val* Sets the significance level (default 0.05).

/CONW=*cWave* Performs a multiple contrasts test. *cWave* has one point for each input wave. The *cWave* value is 1 to include the corresponding (zero based) input wave in the first group, 2 to include the wave in the second group, or zero to exclude the wave.

The contrast is defined as the difference between the normalized sum of the ranks of the first group and that of the second group. If *cWave*={0,1,1,1,2}, then the contrast hypothesis  $H_0$  corresponds to:

$$\frac{\bar{X}_1 + \bar{X}_2 + \bar{X}_3}{3} - \bar{X}_4 = 0$$

For each pair of waves (*i*, *j*) with  $i \neq j$ , it computes

$$SE_{ij} = \sqrt{s^2 \left( \frac{1}{n_j} + \frac{1}{n_i} \right)}, \quad s^2 = \sum_{i=1}^W \sum_{j=0}^{n_i-1} X_j^2 - \sum_{i=1}^W \frac{\left( \sum_{j=0}^{n_i-1} X_j \right)^2}{n_i}$$

the statistic

$$S = \frac{\left| \sum_{i=0}^{m-1} c_i \bar{X}_i \right|}{SE}$$

the critical value, and a result field which is set to 1 if  $H_0$  should be accepted or 0 if it should be rejected. *W* is the total number of waves,  $n_i$  and  $\bar{X}_i$  are respectively the number of data points and the average of wave *i*.

/Q No results printed in the history area.

/SWN Creates a text wave, T\_ScheffeDescriptors, containing wave names corresponding to each row of the comparison table (Save Wave Names). Use /T to append the text wave to the last column.

- `/T=k` Displays results in a table.  $k$  specifies the table behavior when it is closed.  
 $k=0$ : Normal with dialog (default).  
 $k=1$ : Kills with no dialog.  
 $k=2$ : Disables killing.  
 The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
- `/WSTR=waveListString`  
 Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.
- `/Z` Ignores errors. `V_flag` will be set to -1 for any error and to zero otherwise.

**Details**

The default of `StatsScheffeTest` (also known as the S test) tests the hypotheses of equality of means for each possible pair of samples. It is not as powerful as Tukey's test (`StatsTukeyTest`) and is more useful for hypotheses formulated as multiple contrasts (see `/CONT`).

## StatsSignTest

**StatsSignTest** [*flags*] *wave1*, *wave2*

The `StatsSignTest` operation performs the sign test for paired-sample data contained in *wave1* and *wave2*.

**Flags**

- `/ALPH=val` Sets the significance level (default 0.05).  
`/Q` No results printed in the history area.  
`/T=k` Displays results in a table.  $k$  specifies the table behavior when it is closed.  
 $k=0$ : Normal with dialog (default).  
 $k=1$ : Kills with no dialog.  
 $k=2$ : Disables killing.  
`/Z` Ignores errors. `V_flag` will be set to -1 for any error and to zero otherwise.

**Details**

The input waves must be the equal length, real numeric waves and must not contain any NaNs or INFs. Results are saved in the wave `W_SignTest` and are optionally displayed in a table. `StatsSignTest` computes the differences in each pair and counts the total number of entries with positive and negative differences, and tests the results using a binomial distribution. When the number of data pairs exceeds 1024 it uses a normal approximation to the binomials for calculating the probabilities and the power of the test.

Chapter III-12, **Statistics** for a function and operation overview.

## StatsSpearmanRhoCDF

**StatsSpearmanRhoCDF** (*r*, *N*)

The `StatsSpearmanRhoCDF` function returns the cumulative distribution function for Spearman's  $r$ , which is used in rank correlation test. It is valid for  $N > 1$  and  $-1 \leq r \leq 1$ . The distribution is mostly computed using the Edgeworth series expansion.

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRankCorrelationTest**, **StatsInvSpearmanCDF**, and **StatsKendallTauTest** functions.

## StatsSRTest

### StatsSRTest [ flags ] srcWave

The StatsSRTest operation performs a parametric or nonparametric serial randomness test on *srcWave*, which must contain finite numerical data. The null hypothesis of the test is that the data are randomly distributed. Output is to the W\_StatsSRTest wave in the current data folder.

### Flags

/ALPH = val	Sets the significance level (default val=0.05).
/GCD	Tests the output of a random number generator (RNG). <i>srcWave</i> consists of values between 0 and $2^{32}$ (converted to unsigned 32-bit integers). GCD computes the gcd for consecutive pairs of data in <i>srcWave</i> . The number of steps in the GCD and the distribution of the GCD's are compared with ideal distributions and corresponding P values are reported. This test is part of Marsaglia's Die-Hard battery of tests. P-values close to either 0 or 1 indicate a nonideal RNG. You should use the reported minimum and maximum values to check that the input is indeed in the proper range. Typically <i>srcWave</i> consists of at least $1e6$ entries.
/NP	Performs a nonparametric serial randomness test by counting the numbers of runs up and down and computing the probability that such a value is obtained by chance.
/P	Performs a parametric serial randomness test.
/Q	No results printed in the history area.
/T=k	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing.
/Z	Ignores errors.

### Details

The parametric test for serial randomness is according to Young. *C* is given by

$$C = 1 - \frac{\sum_{i=0}^{n-1} (X_i - X_{i+1})^2}{2 \sum_{i=0}^{n-1} (X_i - \bar{X})^2}$$

where  $\bar{X}$  is the mean and *n* is the number of points in *srcWave*. The critical value is obtained from mean square successive difference distribution **StatsInvCMSSDCDF**. For more than 150 points, StatsSRTest uses the normal approximation and provides the critical values from the normal distribution. For samples from a normal distribution, *C* is symmetrically distributed about 0 with positive values indicating positive correlation between successive entries and negative values corresponding to negative correlation.

The nonparametric test consists of counting the number of runs that are successive positive or successive negative differences between sequential data. If two sequential data are the same it computes two numbers of runs by considering the two possibilities where the equality is replaced with either a positive or a negative difference. The results of the operation include the number of runs up and down, the number of unchanged values (the number of places with no difference between consecutive entries), the size of the longest run and its associated probability, the number of converted equalities, and the probability that the number of runs is less than or equal to the reported number (**StatsRunsCDF**). When equalities are encountered the operation computes the probabilities that the computed number of runs or less can be found in an equivalent random sequence.

Converted equalities are those with the same sign on both sides so that when we replace the equality by the opposite sign we increase the number of runs. The equalities that are not converted are found between two

different signs and therefore regardless of the sign that we give them they do not affect the total number of runs. We implicitly assume that the data does not contain more than one sequential equalities.

The longest run is determined without taking into account equalities or their conversions. The probability of the longest run is computed from Equation 6 of Olmstead, which is accurate within 0.001 when the number of runs is 5 or more. This probability applies to either positive or negative differences and should be divided by two if a specific sign is selected.

## StatsStudentCDF

### StatsStudentCDF(*t*, *n*)

The StatsStudentCDF function returns the Student (uniform) cumulative distribution function

$$F(t, n) = \begin{cases} \frac{1}{2} \left\{ 1 + I \left( \frac{n}{2}, \frac{1}{2}; 1 \right) - I \left( \frac{n}{2}, \frac{1}{2}; \frac{n}{n+t^2} \right) \right\} & t > 0 \\ \frac{1}{2} \left\{ 1 + I \left( \frac{n}{2}, \frac{1}{2}; \frac{n}{n+t^2} \right) - I \left( \frac{n}{2}, \frac{1}{2}; 1 \right) \right\} & t < 0 \\ \frac{1}{2} & t = 0 \end{cases}$$

where  $n > 0$  is degrees of freedom and is the incomplete beta function **betai**.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsStudentPDF** and **StatsInvStudentCDF** functions.

## StatsStudentPDF

### StatsStudentPDF(*t*, *n*)

The StatsStudentPDF function returns the Student (uniform) probability distribution function

$$f(t, n) = \frac{\left( \frac{n}{n+t^2} \right)^{(n+1)/2}}{\sqrt{n} B \left( \frac{n}{2}, \frac{1}{2} \right)}$$

where  $n > 0$  is degrees of freedom and  $B()$  is the **beta** function.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsStudentCDF** and **StatsInvStudentCDF** functions.

### StatsTopDownCDF

#### **StatsTopDownCDF(r, N)**

The StatsTopDownCDF function returns the cumulative distribution function for the top-down correlation coefficient. It is computationally intensive because it must evaluate many permutations [ $O((n!)^2)$ ]. It exactly calculates the distribution for  $3 \leq N \leq 7$ ; outside this range it uses Monte-Carlo estimation for  $8 \leq N \leq 50$  and asymptotic Normal approximation for  $N > 50$ . The Monte-Carlo estimate uses 1e6 random permutations fitted with two 9-order polynomials for the range  $[-1,0]$  and  $[0,1]$ . The results are within 0.2% of exact values where known.

Iman, R.L., and W.J. Conover, A measure of top-down correlation, *Technometrics*, 29, 351-357, 1987.

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRankCorrelationTest** and **StatsInvTopDownCDF** functions.

### StatsTriangularCDF

#### **StatsTriangularCDF(x, a, b, c)**

The StatsTriangularCDF function returns the triangular cumulative distribution function

$$F(x, a, b, c) = \begin{cases} \frac{(x-a)^2}{(b-a)(c-a)} & a \leq x \leq c \\ 1 - \frac{(b-x)^2}{(b-a)(c-a)} & c \leq x \leq b \end{cases}$$

where  $a < c < b$ .

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsTriangularPDF** and **StatsInvTriangularCDF** functions.

### StatsTriangularPDF

#### **StatsTriangularPDF(x, a, b, c)**

The StatsTriangularPDF function returns the triangular probability distribution function

$$f(x, a, b, c) = \begin{cases} \frac{2(x-a)}{(b-a)(c-a)} & a \leq x \leq c \\ \frac{2(b-x)}{(b-a)(c-a)} & c < x < b \\ 0 & \text{otherwise.} \end{cases}$$

where  $a < c < b$ .

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsTriangularCDF** and **StatsInvTriangularCDF** functions.

### StatsTrimmedMean

#### **StatsTrimmedMean(waveName, trimValue)**

The StatsTrimmedMean function returns the mean of the wave *waveName* after removing *trimValue* fraction of the values from both tails of the distribution. *trimValue* is a number in the range  $[0, 0.5]$ . *waveName* can be any real numeric type.

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsQuantiles** and **mean**.

## StatsTTest

**StatsTTest** [*flags*] *wave1* [, *wave2*]

The StatsTTest operation performs two kinds of T-tests: the first compares the mean of a distribution with a specified mean value (/MEAN) and the second compares the means of the two distributions contained in *wave1* and *wave2*, which must contain at least two data points, can be any real numeric type, and can have an arbitrary number of dimensions. Output is to the W\_StatsTTest wave in the current data folder or optionally to a table.

### Flags

- /ALPH = *val* Sets the significance level (default *val*=0.05).
- /CI Computes the confidence intervals for the mean(s).
- /DFM=*m* Specifies method for calculating the degrees of freedom.  
*m*=0: Default; computes equivalent degrees of freedom accounting for possibly different variances.  
*m*=1: Computes equivalent degrees of freedom but truncates to a smaller integer.  
*m*=2: Computes degrees of freedom by  $DF=n_1+n_2-2$ , where *n* is the sum of points in the wave. Appropriate when variances are equal.
- /MEAN=*meanV* Compares *meanV* with the mean of the distribution in *wave1*. Outputs are the number of points in the wave, the degrees of freedom (accounting for any NaNs), the average, standard deviation ( $\sigma$ ),  

$$s_x = \frac{\sigma}{\sqrt{DF+1}} \text{ the statistic } t = \frac{\bar{X} - \text{meanV}}{s_x}$$
and the critical value, which depends on /TAIL.
- /PAIR Specifies that the input waves are pairs and computes the difference of each pair of data to get the average difference  $\bar{d}$  and the standard error of the difference  $S_{\bar{d}}$ . The t statistic is the ratio of the two  

$$t = \frac{\bar{d}}{S_{\bar{d}}}$$
In this case  $H_0$  is that the difference  $\bar{d}$  is zero.  
This mode does not support /CI and /DFM.
- /Q No results printed in the history area.
- /T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.  
*k*=0: Normal with dialog (default).  
*k*=1: Kills with no dialog.  
*k*=2: Disables killing.  
The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
- /TAIL=*tc* Specifies  $H_0$  for /CIDX.  
*tc*=1: One tailed test ( $\mu_1 \leq \mu_2$ ).  
*tc*=2: One tailed test ( $\mu_1 \geq \mu_2$ ).  
*tc*=4: Default; two tailed test ( $\mu_1 \neq \mu_2$ ).
- /Z Ignores errors. V\_flag will be set to -1 for any error and to zero otherwise.

### Details

When comparing the mean of a single distribution with a hypothesized mean value, you should use /MEAN and only one wave (*wave1*). If you use two waves StatsTTest performs the T-test for the means of the corresponding distributions (which is incompatible with /MEAN).

When comparing the means of two distributions, the t statistic is given by

$$t = \frac{\bar{X}_1 - \bar{X}_2}{\sqrt{s_1^2 + s_2^2}} \text{ where } s_i^2 \text{ are variances, } n_i \text{ the number of samples, and } \bar{X}_i \text{ the averages of the waves.}$$

## StatsTukeyTest

---

The different test are:

$H_0$	Rejection Condition
$\mu_1 = \mu_2$	$ t  \geq Tc(\alpha, \nu)$
$\mu_1 > \mu_2$	$t \leq Tc(\alpha, \nu)$
$\mu_1 < \mu_2$	$t \geq Tc(\alpha, \nu)$

$Tc$  is the critical value and  $\nu$  is the effective number of degrees of freedom, which accounts for possibly unequal variances:

$$\nu = \frac{\left( \frac{s_1^2}{n_1} + \frac{s_2^2}{n_2} \right)^2}{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}$$

The critical values ( $Tc$ ) are computed by numerically by solving for the argument at which the cumulative distribution function (CDF) equals the appropriate values for the tests. The CDF is given by

$$F(x) = \begin{cases} \frac{1}{2} \text{betainc}\left(\frac{\nu}{2}, \frac{1}{2}, \frac{\nu}{\nu+x^2}\right) & x < 0 \\ 1 - \frac{1}{2} \text{betainc}\left(\frac{\nu}{2}, \frac{1}{2}, \frac{\nu}{\nu+x^2}\right) & x \geq 0 \end{cases}$$

To get the critical value for the upper one-tail test we solve  $F(x)=1-\alpha$ . For the lower one-tail test we solve for  $x$  the equation  $F(x)=\alpha$ . In the two-tailed test the lower critical value is a solution for  $F(x)=\alpha/2$  and the upper critical value is a solution for  $F(x)=1-\alpha/2$ .

The T-test assumes both samples are randomly taken from normal population distributions.

## StatsTukeyTest

**StatsTukeyTest** [*flags*] [*wave1, wave2, ... wave100*]

The StatsTukeyTest operation performs multiple comparison Tukey (HSD) test and optionally the Newman-Keuls test. Output is to the M\_TukeyTestResults wave in the current data folder. StatsTukeyTest usually follows **StatsANOVA1Test**.

### Flags

/ALPH = <i>val</i>	Sets the significance level (default <i>val</i> =0.05).
/NK	Computes the Newman-Keuls test.
/Q	No results printed in the history area.
/SWN	Creates a text wave, T_TukeyDescriptors, containing wave names corresponding to each row of the comparison table (Save Wave Names). Use /T to append the text wave to the last column.
/T= <i>k</i>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing.
/WSTR= <i>waveListString</i>	Specifies a string containing a semicolon-separated list of waves that contain sample data. Use <i>waveListString</i> instead of listing each wave after the flags.
/Z	Ignores errors.

**Details**

Inputs to StatsTukeyTest are two or more 1D numeric waves (one wave for each group of samples) containing any numbers of points but with at least two or more valid entries.

The contents of the M\_TukeyTestResults columns are: the first contains the difference between the group means  $X_i - X_j$ , the second contains SE (supports unequal number of points), the third contains the q statistic for the pair, and the fourth contains the critical q value, the fifth contains the conclusion with 0 to reject  $H_0$  ( $\mu_i = \mu_j$ ) or 1 to accept  $H_0$ , with /NK, the sixth contains the  $p$  values

$$p = \text{rank}[\bar{X}_i] - \text{rank}[\bar{X}_j] + 1$$

the seventh contains the critical values, and the eighth contains the Newman-Keuls conclusion (with 0 to reject and 1 to accept  $H_0$ ). The order of the rows is such that all possible comparisons are computed sequentially starting with the comparison of the group having the largest mean with the group having the smallest mean.

V\_flag will be set to -1 for any error and to zero otherwise.

Chapter III-12, **Statistics** for a function and operation overview; **StatsANOVA1Test**, **StatsScheffeTest**, and **StatsDunnnettTest**.

**StatsUSquaredCDF****StatsUSquaredCDF(u2, n, m, method, useTable)**

The StatsUSquaredCDF function returns the cumulative distribution function for Watson's  $U^2$  with parameters  $u2$  ( $U^2$  statistic) and integer sample sizes  $n$  and  $m$ . The calculation is computationally intensive, on the order of  $\text{binomial}(n+m, m)$ . Use a nonzero value for *useTable* to search a built-in table of values. If  $n$  and  $m$  cannot be found in the table, it will proceed according to *method*:

<i>method</i>	What It Does
0	Exact computation using Burr algorithm (could be slow).
1	Tiku approximation using chi-squared.
2	Use built-in table only and return a NaN if not in table.

For large  $n$  and  $m$ , consider using the Tiku approximation. To abort execution, press Command-period (*Macintosh*) or Ctrl+Break (*Windows*).

Precomputed tables, using the algorithm described by Burr, contain these values:

<i>n</i>	<i>m</i>
4	4-30
5	5-30
6	6-30
7	7-30
8	8-26
9	9-22
10	10-18
11	11-16
12	12-14
13	13

## StatsVariancesTest

---

Because  $n$  and  $m$  are interchangeable,  $n$  should always be the smaller value. For  $n > 8$  the upper limit in the table matched the maximum that can be computed using the Burr algorithm. There is no point in using method 0 with  $m$  values exceeding these limits.

## StatsVariancesTest

**StatsVariancesTest** [*flags*] [*wave1, wave2, ... wave100*]

The StatsVariancesTest operation performs Bartlett's or Levene's test to determine if wave variances are equal. Output is to the `W_StatsVariancesTest` wave in the current data folder or optionally to a table.

### Flags

`/ALPH = val` Sets the significance level (default  $val=0.05$ ).

`/METH=m` Specifies the test type.

$m=0$ : Bartlett test (default).

$m=1$ : Levene's test using the mean.

$m=2$ : Modified Levene's test using the median.

$m=3$ : Modified Levene's test using the 10% trimmed mean.

`/Q` No results printed in the history area.

`/T=k` Displays results in a table.  $k$  specifies the table behavior when it is closed.

$k=0$ : Normal with dialog (default).

$k=1$ : Kills with no dialog.

$k=2$ : Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

`/WSTR=waveListString` Specifies a string containing a semicolon-separated list of waves that contain sample data. Use `waveListString` instead of listing each wave after the flags.

`/Z` Ignores errors. `V_flag` will be set to -1 for any error and to zero otherwise.

### Details

All tests define the null hypothesis by

$H_0: \sigma_1^2 = \sigma_2^2 = \dots = \sigma_k^2$  against the alternative  $H_a: \sigma_i^2 \neq \sigma_j^2$  for at least one  $i \neq j$

Bartlett's test computes:

$$T = \frac{(n-k)\ln(\sigma_v^2) - \sum_{i=1}^k (n_i - 1)\ln(\sigma_i^2)}{1 + \frac{1}{3(k-1)} \left[ \sum_{i=1}^k \frac{1}{n_i - 1} - \frac{1}{N-k} \right]}$$

where  $\sigma_i^2$  is the variance of the  $i$ th wave,  $N$  is the sum of the points of all the waves,  $n_i$  is the number of points in wave  $i$ , and  $k$  is the number of waves. The weighted variance is given by

$$\sigma_v^2 = \sum_{i=1}^k \frac{(n_i - 1)\sigma_i^2}{N - k}$$

$H_0$  is rejected if  $T$  is greater than the critical value taken from the  $\chi^2$  distribution computed by solving for  $x$ :

$$1 - \alpha = 1 - \text{gamma}\left(\frac{k-1}{2}, \frac{x}{2}\right)$$

Levene's test computes:

$$W = \frac{(N-k) \sum_{i=1}^k n_i (\bar{Z}_i - \bar{Z})^2}{(k-1) \sum_{i=1}^k \sum_{j=1}^{n_i} (Z_{ij} - \bar{Z}_i)^2}, \text{ and } W = \frac{(N-k) \sum_{i=1}^k n_i (\bar{Z}_i - \bar{Z})^2}{(k-1) \sum_{i=1}^k \sum_{j=1}^{n_i} (Z_{ij} - \bar{Z}_i)^2}$$

where  $Z_{ij} = |Y_{ij} - \bar{Y}_i|$ ,  $\bar{Z}_i = \frac{1}{n_i} \sum_{j=1}^{n_i} Z_{ij}$ ,  $\bar{Z} = \frac{1}{N} \sum_{i=1}^k \sum_{j=1}^{n_i} Z_{ij}$ ,  $\bar{Y}_i$  depends on /METH.

$H_0$  is rejected if  $W$  is greater than the critical value from the F distribution computed by solving for  $x$ :

$$1 - \alpha = 1 - \text{beta}\left(\frac{v_2}{2}, \frac{v_1}{2}, \frac{v_2}{v_2 + v_1 x}\right)$$

## StatsVonMisesCDF

### **StatsVonMisesCDF(x, a, b)**

The StatsVonMisesCDF function returns the von Mises cumulative distribution function

$$F(\theta, a, b) = \frac{1}{2\pi I_0(b)} \int_0^\theta \exp(b \cos(x - a)) dx$$

where  $I_0(b)$  is the modified Bessel function of the first kind **bessI**, and  $0 < \theta \leq 2\pi$ ,  $0 < a \leq 2\pi$ , and  $b > 0$ .

## StatsVonMisesNoise

### **StatsVonMisesNoise(a, b)**

The StatsVonMisesNoise function returns a pseudo-random number from a von Mises distribution whose probability density is

$$f(\theta, a, b) = \frac{\exp[b \cos(\theta - a)]}{2\pi I_0(b)} \text{ where } I_0 \text{ is the zeroth order modified Bessel function of the first kind.}$$

## StatsVonMisesPDF

**StatsVonMisesPDF**(*q*, *a*, *b*)

The StatsVonMisesPDF function returns the von Mises probability distribution function

$$f(\theta, a, b) = \frac{\exp(b \cos(\theta - a))}{2\pi I_0(b)}$$

where  $I_0(b)$  is the modified Bessel function of the first kind **bessI**, and  $0 < \theta \leq 2\pi$ ,  $0 < a \leq 2\pi$ , and  $b > 0$ .

## StatsWaldCDF

**StatsWaldCDF**(*x*, *m*, *l*)

The StatsWaldCDF function returns the numerically evaluated inverse Gaussian or Wald cumulative distribution function.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsWaldPDF** function.

## StatsWaldPDF

**StatsWaldPDF**(*x*, *m*, *l*)

The StatsWaldPDF function returns the inverse Gaussian or Wald probability distribution function

$$f(x, \mu, \lambda) = \sqrt{\frac{\lambda}{2\pi x^3}} \exp\left[-\frac{\lambda(x - \mu)^2}{2\mu^2 x}\right] \text{ where } x, m, l > 0.$$

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsWaldCDF** function.

## StatsWatsonUSquaredTest

**StatsWatsonUSquaredTest** [*flags*] *srcWave1*, *srcWave2*

The StatsWatsonUSquaredTest operation performs Watson's nonparametric two-sample  $U^2$  test for samples of circular data. Output is to the *W\_WatsonUtest* wave in the current data folder or optionally to a table.

### Flags

/ALPH = <i>val</i>	Sets the significance level (default <i>val</i> =0.05).
/Q	No results printed in the history area.
/T= <i>k</i>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing. The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
/Z	Ignores errors.

### Details

The input waves, *srcWave1* and *srcWave2*, each must contain at least two angles in radians (mod  $2\pi$ ), can have any number of dimensions, and can be single or double precision; the waves must not contain any NaNs or INFs.

The Watson  $U^2$   $H_0$  postulates that the two samples came from the same population against the different populations alternative. In the calculation, StatsWatsonUSquaredTest ranks the two inputs, accounts for possible ties, computes the test statistic  $U^2$ , and compares it with the critical value. Because of the difficulty of computing the critical values, it always computes first the approximation due to Tiku and if possible it

computes the exact critical value using the method outlined by Burr. You can evaluate the U2 CDF to get more information about the critical region.

V\_flag will be set to -1 for any error and to zero otherwise.

### References

We have found that this method leads to slightly different results depending on the compiler and the system on which it is implemented:

Burr, E.J., Small sample distributions of the two sample Cramer-von Mises' W2 and Watson's U2, *Ann. Mah. Stat. Assoc.*, 64, 1091-1098, 1964.

## StatsWatsonWilliamsTest

**StatsWatsonWilliamsTest** [*flags*] [*srcWave1*, *srcWave2*, *srcWave3*,...]

The StatsWatsonWilliamsTest operation performs the Watson-Williams test for two or more sample means. Output is to the W\_WatsonWilliams wave in the current data folder or optionally to a table.

### Flags

- /ALPH = *val*      Sets the significance level (default *val*=0.05).
- /Q                    No results printed in the history area.
- /T=*k*                Displays results in a table. *k* specifies the table behavior when it is closed.
  - k*=0:    Normal with dialog (default).
  - k*=1:    Kills with no dialog.
  - k*=2:    Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
- /WSTR=*waveListString*      Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.
- /Z                    Ignores errors.

### Details

The StatsWatsonWilliamsTest must have at least two input waves, which contain angles in radians, can be single or double precision, and can be of any dimensionality; the waves must not contain any NaNs or INFs.

The Watson-Williams  $H_0$  postulates the equality of the means from all samples against the simple inequality alternative. The test computes the sums of the sines and cosines from which it obtains a weighted *r* value (*rw*). According to Mardia, you should use different statistics depending on the size of *rw*: for  $rw > 0.95$  use the simple F statistic, but for  $0.95 > rw > 0.7$  you should use the F-statistic with the K correction factor. Otherwise you should use the t-statistic. StatsWatsonWilliamsTest computes both the (corrected) F-statistic and the t-statistic as well as their corresponding critical values.

V\_flag will be set to -1 for any error and to zero otherwise.

## StatsWeibullCDF

**StatsWeibullCDF**(*x*, *m*, *s*, *g*)

The StatsWeibullCDF function returns the Weibull cumulative distribution function

$$F(x, \mu, \sigma, \gamma) = 1 - \exp\left[-\left(\frac{x - \mu}{\sigma}\right)^\gamma\right], \quad x \geq \mu \text{ and } \sigma, \gamma > 0$$

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsWeibullPDF** and **StatsInvWeibullCDF** functions.

## StatsWeibullPDF

**StatsWeibullPDF**(*x*, *m*, *s*, *g*)

The StatsWeibullPDF function returns the Weibull probability distribution function

$$f(x, \mu, \sigma, \gamma) = \frac{\gamma}{\sigma} \left(\frac{x - \mu}{\sigma}\right)^{\gamma-1} \exp\left[-\left(\frac{x - \mu}{\sigma}\right)^\gamma\right]$$

where *m* is the location parameter, *s* is the scale parameter, and *g* is the shape parameter with  $x \geq m$  and  $s, g > 0$ .

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsWeibullCDF** and **StatsInvWeibullCDF** functions.

## StatsWheelerWatsonTest

**StatsWheelerWatsonTest** [*flags*] [*srcWave1*, *srcWave2*, *srcWave3*,...]

The StatsWheelerWatsonTest operation performs the nonparametric Wheeler-Watson test for two or more samples. Output is to the W\_WheelerWatson wave in the current data folder or optionally to a table.

**Flags**

- /ALPH = *val*      Sets the significance level (default *val*=0.05).
- /Q                    No results printed in the history area.
- /T=*k*                Displays results in a table. *k* specifies the table behavior when it is closed.
  - k*=0:    Normal with dialog (default).
  - k*=1:    Kills with no dialog.
  - k*=2:    Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
- /WSTR=*waveListString*      Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.
- /Z                    Ignores errors.

**Details**

The StatsWatsonWilliamsTest must have at least two input waves, which contain angles in radians (mod  $2\pi$ ), can be single or double precision, and can be of any dimensionality; the waves must not contain any NaNs or INFs.

The Wheeler-Watson  $H_0$  postulates that the samples came from the same population. The extension of the test to more than two samples is due to Mardia. The Wheeler-Watson test is not valid for data with ties, in which case you should use Watson's  $U^2$  test.

V\_flag will be set to -1 for any error and to zero otherwise.

**References**

Mardia, K.V., *Statistics of Directional Data*, Academic Press, New York, New York, 1972.

See, in particular, Chapter 27 of:

Zar, J.H., *Biostatistical Analysis*, 4th ed., 929 pp., Prentice Hall, Englewood Cliffs, New Jersey, 1999.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsWatsonUSquaredTest** and **StatsWheelerWatsonTest**.

## StatsWilcoxonRankTest

**StatsWilcoxonRankTest** [*flags*] *waveA*, *waveB*

The StatsWilcoxonRankTest operation performs the nonparametric Wilcoxon-Mann-Whitney two-sample rank test or the Wilcoxon Signed Rank test (for paired data) on *waveA* and *waveB*. Output is to the W\_WilcoxonTest wave in the current data folder or optionally to a table.

**Flags**

/ALPH=*val* Sets the significance level (default *val*=0.05).

/APRX=*m* Sets the approximation method. It computes an exact critical value by default.

*m*=1: Standard normal approximation with ties (Zar P. 151).

*m*=2: Improved normal approximation (Zar P. 152).

Approximations may be appropriate for large sample sizes when computation may take a long time.

/Q No results printed in the history area.

/T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.

*k*=0: Normal with dialog (default).

*k*=1: Kills with no dialog.

*k*=2: Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

/TAIL=*tail* Specifies the tail tested.

*tail*=1: Lower tail.

*tail*=2: Upper tail.

*tail*=4: Two tail.

You can perform any combination of tests by adding their corresponding tail values (/TAIL=7 tests all tail possibilities). Note that H0 changes according to the selected tail.

/WSRT Performs the Wilcoxon Signed Rank Test for paired data. The testh computes statistics Tp and Tm, lower-tail, upper-tail, and two-tail P-values. If the number of samples is less than 200 it computes exact P-values, otherwise they are computed using the normal approximation. Do not use /ALPH, /APRX, and /TAIL with this flag.

/Z Ignores errors.

**Details**

The Wilcoxon-Mann-Whitney test combines the two samples and ranks them to compute the statistic U. If *waveA* has *m* points and *waveB* has *n* points, then *U* is given by

$$U = mn + \frac{m(m+1)}{2} - R_1$$

with the corresponding statistic *U'* given by

$$U' = mn + \frac{n(n+1)}{2} - R_2 \text{ where } R_i \text{ is the ranks of data in the } i\text{th wave (ranked in ascending order).}$$

The distribution of *U* is difficult to compute, requiring the number of possible permutations of *m* elements of *waveA* and *n* elements of *waveB* that give rise to *U* values that do not exceed the one computed. The distribution is computed according to the algorithm developed by Klotz. With increasing sample size one can avoid the time consuming distribution computation and use a normal approximation instead. Klotz recommends this approximation for  $N=m+n \sim 100$ .

Use /APRX=2 for the best approximation. The two approximations are discussed by Zar.

## StatsWRCorrelationTest

---

The Wilcoxon Signed Rank Test, or Wilcoxon Paired-Sample Test, ranks the difference between pairs of values and computes the sums of the positive ranks ( $T_p$ ) and the negative ranks ( $T_m$ ). It calculates  $T_p$  and  $T_m$  and P-values for all tail combinations. The P-values are:

P\_lower\_tail    P( $W_p \leq T_p$ )

P\_upper\_tail    P( $W_p \geq T_p$ )

P\_two\_tail      2\*Min(P\_lower\_tail,P\_upper\_tail)

$W_p$  is the generic symbol for the sum of positive ranks for the given number of pairs.

V\_flag will be set to -1 for any error and to zero otherwise.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsAngularDistanceTest** and **StatsKWTest**.

## StatsWRCorrelationTest

**StatsWRCorrelationTest** [ *flags* ] *waveA*, *waveB*

The StatsWRCorrelationTest operation performs a Weighted Rank Correlation test on *waveA* and *waveB*, which contain the ranks of sequential factors. It computes a top-down correlation coefficient using Savage sums as well as the critical and P-values. Output is to the W\_StatsWRCorrelationTest wave in the current data folder or optionally to a table.

### Flags

/ALPH = *val*      Sets the significance level (default *val*=0.05).

/Q                    No results printed in the history area.

/T=*k*                Displays results in a table. *k* specifies the table behavior when it is closed.

*k*=0:      Normal with dialog (default).

*k*=1:      Kills with no dialog.

*k*=2:      Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

/Z                    Ignores errors.

### Details

The StatsWRCorrelationTest input waves must be one-dimensional and have the same length. The waves are 1-based, integer ranks of factors corresponding to the point number. Ranks may have ties in which case you should repeat the rank value. For example, if the second and third entries have the same rank you should enter {1,2,2,4}.  $H_0$  stipulates that the same factors are most important in both groups represented by *waveA* and *waveB*.

The top-down correlation is the sum of the product of Savage sums for each row:

$$r_{TD} = \frac{\sum_{i=1}^n S_{iA} S_{iB} - n}{n - S_i} \text{ where } n \text{ is the number of rows and the Savage sum } S_i \text{ is } S_i = \sum_{j=1}^i 1$$

and  $S_{iA}$  corresponds to the  $S_i$  value of the rank of the data in row ( $i-1$ ) of *waveA*.

## stopMSTimer

### **stopMSTimer** (*timerRefNum*)

The stopMSTimer function frees up the timer associated with the *timerRefNum* and returns the number of elapsed microseconds since startMSTimer was called for this timer.

#### Parameters

*timerRefNum* is the value returned by startMSTimer or the special values -1 or -2. If *timerRefNum* is not valid then stopMSTimer returns 0. Passing -1 returns the clock frequency of the timer and, on the Macintosh, performs a calibration. Passing -2 returns the time in microseconds since the computer was started.

#### Details

If you want to make sure that all timers are free, call stopMSTimer ten times with *timerRefNum* equal to 0 through 9. It is OK to stop a timer that you never started.

On the Macintosh, the first call to stopMSTimer will take longer (approximately 0.1 sec. more) because of a clock frequency calibration. This will also happen when calling with a value of -1. If the extra time for the first call will cause problems, be sure to force the calibration before your first real timing run.

#### Examples

How long does an empty loop take on your computer?

```
Function TestMSTimer()
  Variable timerRefNum
  Variable microSeconds
  Variable n

  timerRefNum = startMSTimer
  if (timerRefNum == -1)
    Abort "All timers are in use"
  endif
  n=10000
  do
    n -= 1
  while (n > 0)
  microSeconds = stopMSTimer(timerRefNum)
  Print microSeconds/10000, "microseconds per iteration"
End
```

#### See Also

The **startMSTimer** and **ticks** functions.

## str2num

### **str2num**(*str*)

The str2num function returns a number represented by the string expression *str*.

#### Details

str2num returns NaN if *str* does not contain the text for a number.

str2num skips leading spaces and tabs.

#### See Also

The **sscanf** operation for more complex parsing jobs.

## Strconstant

### **Strconstant** *ksName*="literal string"

The Strconstant declaration defines the string *literal string* under the name *ksName* for use by other code, such as in a switch construct.

## String

---

### See Also

The **Constant** keyword for numeric types, **Constants** on page IV-38, and **Switch Statements** on page IV-33.

## String

**String** [/G] *strName* [=*strExpr*][, *strName* [=*strExpr*]...]

The String declaration creates string variables and gives them the specified names.

### Flags

/G           Creates a global string. Overwrites any existing string with the same name.

### Details

The string variable is initialized when it is created if you supply the =*strExpr* initializer. You can create more than one string variable at a time by separating the names and optional initializers with commas.

If used in a procedure, the new string is local to that procedure unless the /G (global) flag is used. If used on the command line, String is equivalent to String/G.

*strName* can optionally include a data folder path.

## StringByKey

**StringByKey**(*keyStr*, *kwListStr* [, *keySepStr* [, *listSepStr* [, *matchCase*]])

The StringByKey function returns a substring extracted from *kwListStr* based on the specified key contained in *keyStr*. *kwListStr* should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for *keySepStr* and *listSepStr*.

Use StringByKey to extract a string value from a string containing a "key1:value1;key2: value2;" style list such as those returned by functions like **AxisInfo** or **TraceInfo**.

If the key is not found or if any of the arguments is "" then a zero-length string is returned.

*keySepStr*, *listSepStr*, and *matchCase* are optional; their defaults are ":", ";", and 0 respectively.

### Details

*keyStr* is limited to 255 characters.

*kwListStr* is searched for an instance of the key string bound by *listSepStr* on the left and a *keySepStr* on the right. The text up to the next *listSepStr* is returned.

*kwListStr* is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *keySepStr* and *listSepStr* are always case-sensitive. Searches for *keyStr* in *kwListStr* are usually case-insensitive. Setting the optional *matchCase* parameter to 1 makes the comparisons case sensitive.

Only the first characters of *keySepStr* and *listSepStr* are used.

If *listSepStr* is specified, then *keySepStr* must also be specified. If *matchCase* is specified, *keySepStr* and *listSepStr* must be specified.

### Examples

```
Print StringByKey("BKEY", "AKEY:hello;BKEY:nok-nok") // prints "nok-nok"
Print StringByKey("KY", "KX=1;ky=hello", "=") // prints "hello"
Print StringByKey("KY", "KX:1,KY:joey", ":", ",") // prints "joey"
Print StringByKey("kz", "KZ:1st,kz:2nd", ":", ",") // prints "1st"
Print StringByKey("kz", "KZ:1st,kz:2nd", ":", ",", 1) // prints "2nd"
```

### See Also

The **NumberByKey**, **RemoveByKey**, **ReplaceNumberByKey**, **ReplaceStringByKey**, **ItemsInList**, **AxisInfo**, **IgorInfo**, **SetWindow**, and **TraceInfo** functions.

## stringCRC

**stringCRC**(*inCRC*, *str*)

The stringCRC function returns 32-bit cyclic redundancy check value of bytes in *str* starting with *inCRC* which should be zero for the first (or only) set of bytes.

### Details

Polynomial used is:

$x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^8+x^7+x^5+x^4+x^2+x+1$

See `crc32.c` in the public domain source code for `zlib` for more information.

#### See Also

The `WaveCRC` function.

## StringFromList

**StringFromList**(*index*, *listStr* [, *listSepStr*])

The `StringFromList` function returns the *index*th substring extracted from *listStr*. *listStr* should contain items separated by the *listSepStr* character, such as "abc;def;".

Use `StringFromList` to extract an item from a string containing a list of items separated by a single character, such as those returned by functions like `TraceNameList` or `AnnotationList`, or a line from a delimited text file.

*index* is zero-based (set *index* to zero to get the first item in the string list).

If *index* < 0, or *index* ≥ the number of items in list, or if *listStr* or *listSepStr* is "", then a zero-length string is returned.

*listSepStr* is optional. When omitted, *listSepStr* is presumed to be ";".

#### Details

*listStr* is searched for an instance of the key string bound by *listSepStr* on the left and right. The text between the bounding *listSepStr*s is returned.

*listStr* is treated as if it ends with a *listSepStr* even if it doesn't.

Only the first character of *listSepStr* is used.

#### Examples

```
Print StringFromList(0, "wave0;wave1;")           // prints "wave0"
Print StringFromList(2, "wave0;wave1;")           // prints ""
Print StringFromList(1, "wave0;;wave2")           // prints ""
Print StringFromList(2, "fred\twilma\tbarney", "\t") // prints "barney"
```

A function that applies a unique line style to each trace in the top graph:

```
Function LineStyler()
  String traces= TraceNameList("",";",1)           // Traces in top graph
  String traceName
  Variable i=0
  do
    traceName= StringFromList(i,traces)
    if( strlen(traceName) == 0 )
      break
    endif
    ModifyGraph lstyle($traceName)= mod(i,18)      // 0 to 17, then repeat
    i += 1
  while (1)                                         // exit is via break statement
End
```

A function that converts a string list into a text wave:

```
Function List2Wave()
  String traces= TraceNameList("",";",1)           // Traces in top graph
  Variable n= ItemsInList(traces)
  Make/O/T/N=(n) textWave= StringFromList(p,traces)
End
```

#### See Also

The `AddListItem`, `ItemsInList`, `FindListItem`, `RemoveFromList`, `WaveList`, `WhichListItem`, `StringByKey`, `ListMatch`, `ControlNameList`, `TraceNameList`, `StringList`, `VariableList`, and `FunctionList` functions.

### StringList

**StringList**(*matchStr*, *separatorStr*)

The StringList function returns a string containing a list of global string variables selected based on the *matchStr* parameter. The string variables listed are all in the current data folder.

#### Details

For a string variable name to appear in the output string, it must match *matchStr*. The first character of *separatorStr* is appended to each string variable name as the output string is generated.

The name of each string variable is compared to *matchStr*, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

"*"	Matches all string variable names
"xyz"	Matches name xyz only
"*xyz"	Matches names which end with xyz
"xyz*"	Matches names which begin with xyz
"*xyz*"	Matches names which contain xyz
"abc*xyz"	Matches names which begin with abc and end with xyz

The list contains names only, without data folder paths. Thus, they are not suitable for accessing string variables outside the current data folder.

*matchStr* may begin with the ! character to return windows that do not match the rest of *matchStr*. For example:

"!*xyz"	Matches variable names which <i>do not</i> end with xyz
---------	---

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of *matchStr*.

#### Examples

StringList("*, ";" )	Returns a list of all string variables in the current data folder.
StringList("S_*", ";" )	Returns a list of all string variables in the current data folder whose names begin with "S_".

#### See Also

See the **VariableList** and **WaveList** functions.

### stringmatch

**stringmatch**(*string*, *matchStr*)

The stringmatch function tests *string* for a match to *matchStr*. You may include asterisks in *matchStr* as a wildcard character. Returns 1 to indicate a match, or 0 for no match.

#### Details

*matchStr* is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

"*"	Matches any string.
"xyz"	Matches the string "xyz" only.
"*xyz"	Matches strings ending with "xyz", for instance "abcxyz".
"xyz*"	Matches strings beginning with xyz, for instance "xyzpqr".
"*xyz*"	Matches strings containing xyz, for instance "abcxyzpqr".
"abc*xyz"	Matches strings beginning with abc and ending with xyz, for instance "abcpxyz".

If *matchStr* begins with the ! character, a match is indicated if *string* does *not* match *matchStr*. For example:

"!*xyz"	Matches strings which <i>do not</i> end with xyz.
---------	---

The ! character is considered to be a normal character if it appears anywhere else.

Note that matching is case-insensitive, so "xyz" also matches "XYZ" or "Xyz".

Also note that it is impossible to match an asterisk in *string*: use **GrepString** instead.

Among other uses, the stringmatch function can be used to build your own versions of the **WaveList** function, using **NameOfWave** and stringmatch to qualify names of waves found by **WaveRefIndexed**.

**See Also**

The **GrepString**, **cmpstr**, **strsearch**, **SplitString**, **ListMatch**, and **ReplaceString** functions and the **sscanf** operation.

**strlen****strlen(*str*)**

The **strlen** function returns the number of characters in the string expression *str*.

**strsearch****strsearch(*str*, *findThisStr*, *start* [, *options*])**

The **strsearch** function returns the numeric position of the string expression *findThisStr* in the string expression *str*.

**Details**

**strsearch** performs a case-sensitive search.

**strsearch** returns -1 if *findThisStr* does not occur in *str*.

The search starts from the character position in *str* specified by *start*; 0 is the first character in *str*.

**strsearch** limits *start* to one less than the length of *str*, so it is useful to use **Inf** for *start* when searching backwards to ensure that the search is from the end of *str*.

The optional *options* parameter is a bitmask specifying the search options:

- 1: Search backwards from *start*.
- 2: Ignore case.
- 3: Search backwards and ignore case.

**Examples**

```
String str="This is a test isn't it?"
Print strsearch(str,"test",0)           // prints 10
Print strsearch(str,"TEST",0)          // prints -1
Print strsearch(UpperStr(str),"TEST",0) // prints 10
Print strsearch(str,"TEST",0,2)        // prints 10
Print strsearch(str,"is",0)            // prints 2
Print strsearch(str,"is",3)            // prints 5
Print strsearch(str,"is",Inf,1)        // prints 15
```

**See Also**

The **sscanf** operation and **FindListItem** and **ReplaceString** functions.

See **Setting Bit Parameters** on page IV-11 for details about bit settings.

**strswitch-case-endswitch****strswitch(<*string expression*>)**

**case** <*literal*><*constant*>:

    <*code*>

    [ **break** ]

[ **default**:

    <*code*> ]

**endswitch**

A **strswitch-case-endswitch** statement evaluates a string expression. If a case label matches *string expression*, then execution proceeds with *code* following the matching case label. When none of the cases match, execution will continue at the default label, if it is present, or otherwise the **strswitch** will be exited with no action taken. Note that although the **break** statement is optional, in almost all case statements it will be required for the **strswitch** to work correctly.

**See Also**

**Switch Statements** on page IV-33, **default** and **break** for more usage details.

## STRUCT

---

### STRUCT

**STRUCT** *structureName localName*

STRUCT is a reference that creates a local reference to a Structure accessed in a user-defined function. When a Structure is passed to a user function, it can only be passed by reference, so in the declaration within the function you must use *&localStructName* to define the function input parameter.

#### See Also

**Structures in Functions** on page IV-61 for further information.

See the **Structure** keyword for creating a Structure definition.

### StructGet

**StructGet** [/B=*b*] *structVar*, *waveStruct*[[*colNum*]]

**StructGet** /S [/B=*b*] *structVar*, *strStruct*

The StructGet operation reads binary numeric data from a specified column of a wave or from a string variable and copies the data into the designated structure variable. The source wave or string will have been filled beforehand by **StructPut**.

#### Parameters

*structVar* is the name of an existing structure that is to be filled with new data values.

*waveStruct* is the name of a wave containing binary numeric data that will be used to fill *structVar*. Use the optional *colNum* parameter to specify a column from the structure wave. The contents of *waveStruct* are created beforehand using StructPut.

*strStruct* is the name of a string variable containing binary numeric data. The contents of *strStruct* are created beforehand using StructPut.

#### Flags

/B=*b* Sets the byte ordering for reading of structure data.

*b*=0: Reads in native byte order.

*b*=1: Reads bytes in reversed order.

*b*=2: Default; reads data in big-endian, high-byte order (Motorola/Macintosh).

*b*=3: Reads data in little-endian, low-byte order (Intel/Windows).

/S Reads binary data from a string variable, which was set previously with StructPut.

#### Details

The data that are stored in *waveStruct* and *strStruct* are in binary format so you can not directly view a meaningful representation of their contents by printing them or viewing the wave in a table. To view the contents of *waveStruct* or *strStruct* you must use StructGet to export them back into a structure and then retrieve the members.

If *colNum* is out of bounds it will be clipped to valid values and an error reported. If the row dimension does not match the structure size, as much data as possible will be copied to the structure.

By default, data are read in big-endian, high-byte order (Motorola/Macintosh). This allows data written on one platform to be read on the other.

#### See Also

The **StructPut** operation for writing structure data to waves or strings.

### StructPut

**StructPut** [/B=*b*] *structVar*, *waveStruct*[[*colNum*]]

**StructPut** /S [/B=*b*] *structVar*, *strStruct*

The StructPut operation copies the binary numeric data in a structure variable to a specified column in a wave or to a string variable. The data in the wave or string can be read out into another structure using **StructGet**.

#### Parameters

*structVar* is the name of a structure from which data will be exported.

*waveStruct* is the name of an existing wave to which data will be exported. Use the optional *colNum* parameter to specify a column in *waveStruct* to contain the data. The first column of *waveStruct* will be filled if *colNum* is omitted.

*strStruct* is the name of an existing string variable to which data will be exported.

### Flags

*/B=b* Sets the byte ordering for writing of structure data.

- b=0*: Writes in native byte order.
- b=1*: Writes bytes in reversed order.
- b=2*: Default; writes data in big-endian, high-byte order (Motorola/Macintosh).
- b=3*: Writes data in little-endian, low-byte order (Intel/Windows).

*/S* Writes binary data to a string variable.

### Details

The structure to be exported must contain only numeric data in either integer, floating point, or double precision format. If the structure contains any objects such as String, NVAR, WAVE, etc., then an error will result at compile time.

If needed, StructPut will redimension *waveStruct* to unsigned byte format, will set the number of rows to equal the size of the structure, and set the column dimension large enough to accommodate the size specified by *colNum*. You can think of *waveStruct* as a one-dimensional array of structure contents indexed by *colNum* although the wave is actually two-dimensional with each column containing a copy of a separate structure.

By default, data are written in big-endian, high-byte order (Motorola/Macintosh). This allows data written on one platform to be read on the other.

After you have exported the structure data to *waveStruct* or *strStruct* they will contain binary data that you cannot inspect directly. To view the contents of *waveStruct* or *strStruct*, you must use the original structure or use StructGet to export them into another structure.

### See Also

The **StructGet** operation for reading structure data from waves or strings.

## Structure

### Structure *structureName*

```
memType memName [arraySize] [, memName [arraySize]]
```

...

### EndStructure

The Structure keyword introduces a structure definition in a user function. Within the body of the structure you declare the member type (*memType*) and the corresponding member name(s) (*memName*). Each *memName* may be declared with an optional array size.

### Details

Structure member types (*memType*) can be any of the following Igor objects: Variable, String, WAVE, NVAR, SVAR, FUNCREF, or STRUCT.

Igor structures also support additional member types, as given in the next table, for compatibility with C programming structures and disk files.

Igor Member Type	C Equivalent	Byte Size
char	signed char	1
uchar	unsigned char	1
int16	short int	2
uint16	unsigned short int	2
int32	long int	4

## StrVarOrDefault

---

Igor Member Type	C Equivalent	Byte Size
uint32	unsigned long int	4
float	float	4
double	double	8

The Variable and double types are identical although Variable can be also specified as complex (using the /C flag).

Each structure member may have an optional *arraySize* specification, which gives the number of elements contained by the structure member. The array size is an integer number of 1 to 100 elements.

### See Also

**Structures in Functions** on page IV-61 for further information.

See the **STRUCT** declaration for creating a local reference to a Structure.

## StrVarOrDefault

### **StrVarOrDefault**(*pathStr*, *defStrVal*)

The StrVarOrDefault function checks to see if *pathStr* points to a string variable and if so, it returns its value. If the string variable does not exist, returns *defStrVal* instead.

### Details

StrVarOrDefault initializes input values of macros so they can remember their state without needing global variables to be defined first. Numeric variables use the corresponding numeric function, **NumVarOrDefault**.

### Examples

```
Macro foo(nval,sval)
  Variable nval=NumVarOrDefault("root:Packages:mypack:nvalSav",2)
  String sval=StrVarOrDefault("root:Packages:mypack:svalSav","Hi")

  String dfSav= GetDataFolder(1)
  NewDataFolder/O/S root:Packages
  NewDataFolder/O/S mypack
  Variable/G nvalSav= nval
  String/G svalSav= sval
  SetDataFolder dfSav
End
```

## StudentA

### **StudentA**(*t*, *DegFree*)

The StudentA function returns the area from  $-t$  to  $t$  under the Student's T distribution having *DegFree* degrees of freedom. That is, it returns the probability that a random sample from Student's T is between  $-t$  and  $t$ .

Note that this is the *bi-tail* result. That is, it gives the area from  $-t$  to  $t$ , rather than the cumulative area from  $-\infty$  to  $t$ . It is this latter number that is commonly tabulated- StudentA returns the probability  $1-\alpha$  where the area from  $-\infty$  to  $t$  is the probability  $1-\alpha/2$ .

StudentA tests whether a normally-distributed statistic is significantly different from a certain value. You could use it to test whether an intercept from a line fit is significantly different from zero:

```
Make/O/N=20 Data=0.5*x+2+gnoise(1) // line with Gaussian noise
Display Data
CurveFit line Data /D
print "Prob = ", StudentA(W_coef[0]/W_sigma[0], V_npnts-2)
```

Because the noise is random, the results will differ slightly each time this is tried. When we did it, the result was:

```
Prob = 0.999898
```

which indicates that the intercept of the line fit was different from zero with 99.99 per cent probability.

## StudentT

### **StudentT(Prob, DegFree)**

The StudentT function returns the t value corresponding to an area *Prob* under the Student's T distribution from  $-t$  to  $t$  for *DegFree* degrees of freedom.

Note that this is a *bi-tail* result, which is what is usually desired. Tabulated values of the Student's T distribution are commonly the one-sided result.

StudentT calculates confidence intervals from standard deviations for normally-distributed statistics. For instance, you can use it to calculate a confidence interval for the coefficients from a curve fit:

```
Make/O/N=20 Data=0.5*x+2+gnoise(1)           // line with Gaussian noise
Display Data
CurveFit line Data /D
print "intercept = ", W_coef[0], "±", W_sigma[0]*StudentT(0.95, V_npnts-2)
print "slope = ", W_coef[1], "±", W_sigma[1]*StudentT(0.95, V_npnts-2)
```

### See Also

Chapter III-12, **Statistics** for a function and operation overview.

## Submenu

### **Submenu menuNameStr**

The Submenu keyword introduces a submenu definition. It is used inside a Menu definition. See Chapter IV-5, **User-Defined Menus** for further information.

## sum

### **sum(waveName [, x1, x2])**

The sum function returns the sum of the wave elements for points from  $x=x1$  to  $x=x2$ .

### Details

The X scaling of the wave is used only to locate the points nearest to  $x=x1$  and  $x=x2$ . To use point indexing, replace  $x1$  with `pnt2x(waveName,pointNumber1)`, and a similar expression for  $x2$ .

If  $x1$  and  $x2$  are not specified, they default to  $-\infty$  and  $+\infty$ , respectively.

If the points nearest to  $x1$  or  $x2$  are not within the point range of 0 to `numpts(waveName)-1`, sum limits them to the nearest of point 0 or point `numpts(waveName)-1`.

If any values in the point range are NaN, sum returns NaN.

### Examples

```
Make/O/N=100 data;SetScale/I x 0,Pi,data
data=sin(x)
Print sum(data,0,Pi)           // the entire point range, and no more
Print sum(data)                // same as -infinity to +infinity
Print sum(data,Inf,-Inf)      // +infinity to -infinity
```

The following is printed to the history area:

```
·Print sum(data,0,Pi)           // the entire point range, and no more
  63.0201
·Print sum(data)                // same as -infinity to +infinity
  63.0201
·Print sum(data,Inf,-Inf)      // +infinity to -infinity
  63.0201
```

### See Also

**mean** and **area** functions.

## SVAR

### **SVAR [/Z] localName [= pathToStr][, localName1 [= pathToStr1]]...**

SVAR is a reference that creates a local reference to a global string variable accessed in a user-defined function.

The SVAR reference is required when you access a global string variable in a function. At compile time, the SVAR statement specifies a local name referencing a global string variable. At runtime, it makes the connection between the local name and the actual global variable. For this connection to be made, the global string variable must exist when the SVAR statement is executed.

## SVAR\_Exists

---

When *localName* is the same as the global string variable name and you want to reference a global variable in the current data folder, you can omit *pathToStr*. Prior to Igor Pro 4.0, *pathToStr* was always required.

*pathToStr* can be a full literal path (e.g., root:FolderA:var0), a partial literal path (e.g., :FolderA:var0) or \$ followed by string variable containing a computed path (see **Converting a String into a Reference Using \$** on page IV-48).

If the global variable may not exist at runtime, use the /Z flag and call **SVAR\_Exists** before accessing the variable. The /Z flag prevents Igor from flagging a missing global variable as an error and dropping into the Igor debugger. For example:

```
SVAR/Z nv=<pathToPossiblyMissingStringVariable>
if( SVAR_Exists(sv) )
    <do something with sv>
endif
```

Note that to create a global string variable, you use the **String/G** operation.

### Flags

/Z ignores string reference checking failures.

### See Also

**SVAR\_Exists** function and **Accessing Global Variables and Waves** on page IV-49.

**Runtime Lookup of Globals** on page IV-50.

**Converting a String into a Reference Using \$** on page IV-48.

## SVAR\_Exists

### **SVAR\_Exists**(*name*)

The **SVAR\_Exists** function returns one if the specified SVAR reference is valid or zero if not. Used only in user-defined functions.

For example if, in a user function, you have:

```
SVAR var1= MyGlobalVar
print SVAR_Exists(var1)
```

will print 1 if MyGlobalVar is present in the current data folder.

### See Also

**WaveExists**, **NVAR\_Exists**, and **Accessing Global Variables and Waves** on page IV-49.

## switch-case-endswitch

```
switch(<numeric expression>)
    case <literal><constant>:
        <code>
        [ break ]
    [ default:
        <code> ]
endswitch
```

A switch-case-endswitch statement evaluates a numerical expression. If a case label matches *numerical expression*, then execution proceeds with *code* following the matching case label. When no cases match, execution will continue at the default label, if present, or otherwise the switch will be exited with no action taken. Note that although the break statement is optional, in almost all case statements it will be required for the switch to work correctly.

### See Also

**Switch Statements** on page IV-33, **default** and **break** for more usage details.

## t

## t

The `t` function returns the `T` value for the current chunk of the destination wave when used in a multidimensional wave assignment statement. `T` is the scaled chunk index while `s` is the chunk index itself.

**Details**

Unlike `x`, outside of a wave assignment statement, `t` does not act like a normal variable.

**See Also**

**Waveform Arithmetic and Assignments** on page II-80.

For other dimensions, the `p`, `q`, `r`, and `s` functions.

For scaled dimension indices, the `x`, `y`, and `z` functions.

## TabControl

**TabControl** [/Z] *ctrlName* [*key* [= *value*]][, *key* [= *value*]]...

The `TabControl` operation creates tab panels for controls.

For information about the state or status of the control, use the **ControlInfo** operation.

**Parameters**

*ctrlName* is the name of the `TabControl` to be created or changed.

*key* is one of the following parameters:

`appearance={kind [, platform]}`

Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

*kind* can be one of `default`, `native`, or `os9`.

*platform* can be one of `Mac`, `Win`, or `All`.

See **DefaultGuiControls Default Fonts and Sizes** for how enclosed controls are affected by native `TabControl` appearance.

See **Button** for more appearance details.

`disable=d`

Sets user editability of the control.

*d*=0: Normal.

*d*=1: Hidden.

*d*=2: Draw in gray state; disable control action.

`font="fontName"`

Sets the font used for tabs, e.g., `font="Helvetica"`.

`fsize=s`

Sets the font size for tabs.

`fstyle=fs`

*fs* is a binary coded number with each bit controlling one aspect of the font style as follows:

bit 0: Bold.

bit 1: Italic.

bit 2: Underline.

bit 3: Outline (*Macintosh only*).

bit 4: Shadow (*Macintosh only*).

See **Setting Bit Parameters** on page IV-11 for details about bit settings.

`labelBack=(r,g,b)` or 0

Sets fill color for current tab and the interior. *r*, *g*, and *b* are integers from 0 to 65535. If not set, then interior is transparent and the current tab is filled with the window background. Note that if you use a fill color, draw objects can not be used because they will be covered up.

`noproc`

Specifies that no function is to run when clicking a tab.

`pos={left,top}`

Sets absolute location in pixels.

`proc=procName`

Specifies the function to run when the tab is pressed. Your function must hide and show other controls as desired. The `TabControl` does not do this automatically.

`size={width,height}`

Sets `TabControl` size in pixels.

## TabControl

---

`tabLabel(n)=lbl` Sets *n*th tab label to *lbl*. Set the label of the last tab to "" to reduce the number of tabs.

`userdata(UDName)=UDStr` Sets the unnamed user data to *UDStr*. Use the optional (*UDName*) to specify a named user data to create.

`userdata(UDName)+=UDStr` Appends *UDStr* to the current unnamed user data. Use the optional (*UDName*) to append to the named *UDStr*.

`value=v` Sets current tab number. Tabs count from 0.

`win=winName` Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

### Flags

`/Z` No error reporting.

### Details

The action procedure for a `TabControl` can use a predefined structure `WMTabControlAction` as a parameter to the function. The control will use this more efficient method when the function properly matches the structure prototype for a `TabControl`, otherwise it will use the old-style method.

A `TabControl` action procedure using a structure has the format:

```
Function newActionProcName(TC_Struct)
    STRUCT WMTabControlAction &TC_Struct
    ...
End
```

For a `TabControl`, the `WMTabControlAction` structure has members as described in the following table:

**WMTabControlAction Structure Members**

Member	Description						
<code>char ctrlName[MAX_OBJ_NAME+1]</code>	Control name.						
<code>char win[MAX_WIN_PATH+1]</code>	Host (sub)window.						
<code>STRUCT Rect winRect</code>	Local coordinates of host window.						
<code>STRUCT Rect ctrlRect</code>	Enclosing rectangle of the control.						
<code>STRUCT Point mouseLoc</code>	Mouse location.						
<code>Int32 eventCode</code>	Event that executed the procedure.						
	<table><thead><tr><th>eventCode</th><th>Event</th></tr></thead><tbody><tr><td>-1</td><td>Control being killed</td></tr><tr><td>2</td><td>Mouse up</td></tr></tbody></table>	eventCode	Event	-1	Control being killed	2	Mouse up
eventCode	Event						
-1	Control being killed						
2	Mouse up						
<code>Int32 eventMod</code>	Bitfield of modifiers. See description of <code>MODIFIERS : flags</code> for <b>SetWindow</b> under <b>Unnamed Hooks</b> on page V-505.						
<code>String userdata</code>	Primary (unnamed) user data. If this changes, it is written back automatically.						
<code>Int32 tab</code>	Tab number.						

Action functions should respond only to documented `eventCode` values. Other event codes may be added along with more fields. Although the return value is not currently used, action functions should always return zero.

The constants used to specify the size of structure `char` arrays are internal to Igor Pro and may change.

When clicking a `TabControl` with the selector arrow, click in the title region. The control will not be selected if you click in the body. This is to make it easier to select controls in the body rather than the `TabControl` itself.

TabControls may be used to simplify complex control panels. If you are not already familiar with the concept of a TabControl, see **Modifying Axes** on page II-242 for an illustration of tabs as used in the Modify Axis dialog.

Designing a TabControl with all the accompanying interior controls can be somewhat difficult. Here is a suggested technique:

First, create and set the size and label for one tab. Then create the various controls for this first tab. Before starting on the 2nd tab, create the TabControl's procedure so that it can be used to hide the first set of controls. Then add the 2nd tab, click it to run your procedure and start adding controls for this new tab. When done, update your procedure so the new controls will be hidden when you start on the third tab. You may find it useful to create a recreation macro of your panel to get a convenient listing of the controls. Here is an example:

(The commands given include size and position information obtained by manual adjustment.)

1. Create a panel and a TabControl:

```
NewPanel /W=(150,50,478,250)
ShowTools
TabControl foo,pos={29,38},size={241,142},tabLabel(0)="first tab",value=0
```

2. Add a few controls to the interior of the TabControl:

```
Button button0,pos={52,72},size={50,20},title="First"
CheckBox check0,pos={52,105},size={102,15},title="Check first",value=0
```

3. Write a function:

```
Function fooProc(name,tab)
  String name
  Variable tab
  Button button0,disable= (tab!=0)
  CheckBox check0,disable= (tab!=0)
End
```

4. Set proc and add a new tab:

```
TabControl foo,proc=fooProc,tabLabel(1)="second tab"
```

5. Click the second tab (which hides the first tab's controls) and then add new controls like so:

```
Button button1,pos={58,73},size={50,20},title="Second"
CheckBox check1,pos={60,105},size={114,15},title="Check second",value= 0
```

6. Finally, change `fooProc` by adding these lines at the end:

```
Button button1,disable= (tab!=1)
CheckBox check1,disable= (tab!=1)
```

## Table

### Table

Table is a procedure subtype keyword that identifies a macro as being a table recreation macro. It is automatically used when Igor creates a window recreation macro for a table. See **Procedure Subtypes** on page IV-149 and **Killing and Recreating a Table** on page II-179 for details.

## TableStyle

### TableStyle

TableStyle is a procedure subtype keyword that puts the name of the procedure in the Style pop-up menu of the New Table dialog and in the Table Macros menu. See **Table Style Macros** on page II-211 for details.

## TableInfo

### TableInfo(winNameStr, itemIndex)

The TableInfo function returns a string containing a semicolon-separated list of keywords and values that describe a column in a table or overall properties of the table. The main purpose of TableInfo is to allow an advanced Igor programmer to write a procedure which formats or arranges a table or which manipulates the table selection.

## TableInfo

---

### Parameters

*winNameStr* is the name of an existing table window or "" to refer to the top table.

*itemIndex* is one of the following:

<i>itemIndex</i> Value	Returns
-2	Information about the table as a whole.
-1	Information about the Point column
$\geq 0$	Information about a column other than the Point column. 0 refers to the first column after the Point column, 1 refers to the second column after the Point column, and so on.

---

TableInfo returns "" in the following situations:

*winNameStr* is "" and there are no table windows.

*winNameStr* is a name but there are no table windows with that name.

*itemIndex* not -2 and is out of range for an existing column.

### Details

If *itemIndex* is -2, the returned string describes the table as a whole and contains the following keywords, with a semicolon after each keyword-value pair.

Keyword	Information Following Keyword
TABLERNAME	The name of the table.
HOST	The host specification of the table's host window if it is a subwindow or "" if it is a top-level table window.
ROWS	Number of used rows in the table.
COLUMNS	Number of used columns in the table including the Point column.
SELECTION	A description of the table selection as you would specify it when invoking the ModifyTable operation's selection keyword.
FIRSTCELL	An identification of the first visible data cell in the top/left corner of the table in row-column format. The first data cell is at location 0, 0.
LASTCELL	An identification of the last visible data cell in the bottom/right corner of the table in row-column format.
TARGETCELL	An identification of the target (highlighted) data cell in row-column format.
ENTERING	1 if an entry has been started in the entry line, 0 if not.

---

If *itemIndex* is -1 up to but not including the number of used columns to the right of the Point column, the returned string describes the specified column and contains the following keywords, with a semicolon after each keyword-value pair.

Keyword	Information Following Keyword
TABLERNAME	The name of the table.
HOST	The host specification of the table's host window if it is a subwindow or "" if it is a top-level table window.
COLUMNNAME	Name of the column as you would specify it to the Edit operation if you were creating a table showing just the column of interest.
TYPE	Column's type which will be one of the following: Unused, Point, Index, Label, Data, RealData, ImagData. "Index" identifies a index column such as the X values of a wave. "Label" identifies a column of dimension labels. "Data" identifies a data column of a scalar wave. RealData and ImagData identify a real or imaginary column of a complex wave.

---

Keyword	Information Following Keyword
INDEX	Column's position. -1 refers to the Point column, 0 to the first data column, and so on.
DATATYPE	Numeric data type of the wave or zero for text waves. See WaveType for a definition of data type codes.
WAVE	A full data folder path to the wave displayed in the column or "" for the Point column.
COLUMNS	The total number of columns in the table from the wave for the column for which you are getting information. This can be used to skip over all of the columns of a multidimensional wave.
HDIM	The wave dimension displayed horizontally as you move from one column to the next. 0 means rows, 1 means columns, 2 means layers, 3 means chunks.
VDIM	The wave dimension displayed vertically in the column. 0 means rows, 1 means columns, 2 means layers, 3 means chunks.
TITLE	As specified for the ModifyTable operation's title keyword.
WIDTH	Column's width in points.
FORMAT	As specified for the ModifyTable operation's format keyword.
DIGITS	As specified for the ModifyTable operation's digits keyword.
SIGDIGITS	As specified for the ModifyTable operation's sigDigits keyword.
TRAILINGZEROS	As specified for the ModifyTable operation's trailingZeros keyword.
SHOWFRACSECONDS	As specified for the ModifyTable operation's showFracSeconds keyword.
FONT	The name of the column's font.
SIZE	Column's font size.
STYLE	As specified for the ModifyTable operation's style keyword.
ALIGNMENT	0=left, 1=center, 2=right.
RGB	The column's color in R,G,B format.
ELEMENTS	As specified for the ModifyTable operation's elements keyword.

### Examples

This example makes the table's target cell advance by one position within the range of selected cells each time it is called. To try it, create a table, select a range of cells and then run the function using the Macros menu.

```
Menu "Macros"
  "Test/1", /Q, AdvanceTargetCell("")
End

Function AdvanceTargetCell(tableName)
  String tableName           // Name of table or "" for top table.
  String info = TableInfo(tableName, -2)
  if (strlen(info) == 0)
    return -1                // No such table
  endif

  String selectionInfo
  selectionInfo = StringByKey("SELECTION", info)
  Variable fRow, fCol, lRow, lCol, tRow, tCol
  sscanf selectionInfo, "%d,%d,%d,%d,%d,%d", fRow, fCol, lRow, lCol, tRow, tCol
  tCol += 1
  if (tCol > lCol)
    tCol = fCol
    tRow += 1
    if (tRow > lRow)
```

## Tag

---

```
        tRow = fRow
    endif
endif
ModifyTable selection=(-1, -1, -1, -1, tRow, tCol)
End
```

### See Also

The **ModifyTable** operation.

## Tag

**Tag** [*flags*] [*traceOrAxisName*, *xAttach* [, *textStr*]]

The Tag operation puts a tag on the target or named graph window or subwindow. A tag is an annotation that is attached to a particular point on a trace, image, waterfall plot, or axis in a graph.

### Parameters

*traceOrAxisName* is an optional trace or axis name. A trace name can be optionally followed by the # character and an instance number in order to distinguish multiple instances of the same wave in a graph. It identifies the trace or image to which the tag is to be attached. An axis name can be one of the standard axis names (Bottom, Top, Left, or Right) or a user-defined custom axis name.

A string containing *traceOrAxisName* must be used with the \$ operator to specify *traceOrAxisName*.

*xAttach* is the X value of the point on the trace to which the tag is to be attached. For a multidimensional image, it is the linear index into the matrix array. For an axis, *xAttach* can be the X or Y point depending on the particular axis to which the tag is attached; specifying NaN for *xAttach* will center the tag on the axis.

*textStr* is the text that is to appear in the tag.

### Flags

*/A=anchorCode* Specifies position of tag anchor point.

<i>anchorCode</i>	Position	<i>anchorCode</i>	Position
LT	left top	RT	right top
LC	left center	RC	right center
LB	left bottom	RB	right bottom
MT	middle top		
MC	middle center (default)		
MB	middle bottom		

*anchorCode* is a literal, *not* a string.

The anchor point is on the tag itself. Any line or arrow drawn from the tag to the wave starts at the tag's anchor point. The anchor point also determines the precise spot on the tag which represents its position.

*/B=(r,g,b)* Sets color of the tag's background. *r*, *g*, and *b* specify the amount of red, green, and blue as an integer from 0 to 65535.

*/B=b*

- b=0*: Opaque background.
- b=1*: Transparent background.
- b=2*: Same background as the graph plot area background.
- b=3*: Same background as the window background.

*/C* Changes the existing tag.

*/F=frame*

- frame=0*: No frame.
- frame=1*: Underline frame.
- frame=2*: Box frame.

*/G=(r,g,b)* Sets color of the text in the tag. *r*, *g*, and *b* specify the amount of red, green, and blue as an integer from 0 to 65535.

---

<i>/H=legendSymbolWidth</i>	<i>legendSymbolWidth</i> sets width of the legend symbol (the sample line or marker) in points. Use 0 for the default, automatic width.
<i>/I=i</i>	<p><i>i =1:</i> Tag will be invisible if it is “off screen”. “Off screen” means that its attachment point or any part of the tag’s text is off screen. This is esthetically pleasing but gives you nothing to grab if you want to drag the tag back on screen.</p> <p><i>i =0:</i> Tag will always be visible. If it is “off screen”, it appears at the extreme edge of the graph.</p>
<i>/K</i>	Kills existing tag.
<i>/L=line</i>	<p><i>line=0:</i> No line from tag to attachment point.</p> <p><i>line=1:</i> Line connecting tag to attachment point.</p> <p><i>line=2:</i> Line with arrow pointing from tag to attachment point.</p>
<i>/LS= linespace</i>	Specifies a tweak to the normal line spacing where <i>linespace</i> is points of extra (plus or minus) line spacing. For negative values, a blank line may be necessary to avoid clipping the bottom of the last line.
<i>/M[=saMeSize]</i>	<p><i>/M</i> or <i>/M=1</i> specifies that legend markers should be the same size as the marker in the graph.</p> <p><i>/M=0</i> turns same-size mode off so that the size of the marker in the legend is based on text size.</p>
<i>/N=name</i>	Specifies name of the tag to create or change.
<i>/O=rot</i>	<p>Sets the text rotation in degrees counterclockwise. Valid values are -90, 0, 90, 180, or 270.</p> <p>0 is normal horizontal left-to-right text.</p> <p>90 is vertical bottom-to-top text, etc.</p>
<i>/P=tipOffset</i>	Sets the offset from the tip of a tag’s line or arrow to the point on the wave that it is tagging. <i>tipOffset</i> is a positive number from 0 to 200 in points. If <i>tipOffset=0</i> (default), it automatically chooses an appropriate offset.
<i>/Q[=contourInstance]</i>	<p>Associates a tag with a particular contour level trace in a graph recreation macro. Of interest mainly to hard-core programmers.</p> <p>When “=<i>contourInstance</i>” is present, <i>/Q</i> associates the tag with the contour wave. Igor will feel free to change or delete the tag, as appropriate, when it recalculates the contour (because you changed the contour data or appearance, the graph size or the axis range). <i>contourInstance</i> is a contour instance name, such as <i>zWave</i> or <i>zWave#1</i> if you have the same wave contoured twice in the graph.</p> <p><i>/Q</i> by itself, with “=<i>contourInstance</i>” not present, disassociates the tag from the contour wave. Igor will no longer modify or delete the tag (unless the contour level to which it is attached is deleted). If you manually tweak a contour label, using the Modify Annotation dialog, Igor uses this flag.</p>
<i>/R=newName</i>	Renames the tag.
<i>/S=style</i>	<p><i>style=0:</i> Single frame.</p> <p><i>style=1:</i> Double frame.</p> <p><i>style=2:</i> Triple frame.</p> <p><i>style=3:</i> Shadow frame.</p>
<i>/T=tabSpec</i>	<i>tabSpec</i> is a single number in points, such as <i>/T=72</i> , for evenly spaced tabs or a list of tab stops in points such as <i>/T={50, 150, 225}</i> .
<i>/TL=extLineSpec</i>	<p>Specifies extended tag line parameters similar to the <b>SetDrawEnv</b> arrow settings.</p> <p><i>extLineSpec</i> = {<i>keyword</i> = <i>value</i>,...} or zero to turn off all extended specifications.</p> <p>Valid <i>keyword-value</i> pairs are:</p> <p><i>len=l</i> Length of arrow head in points (<i>l=0</i> for auto).</p> <p><i>fat=f</i> Width to length ratio of arrow head (default is 0.5 same as <i>f=0</i>).</p> <p><i>style=s</i> Sets barb side mode (see <b>SetDrawEnv</b> <i>astyle</i> for values).</p> <p><i>shar =s</i> Sets sharpness between -1 and 1 (default is 0; blunt).</p> <p><i>frame=f</i> Sets frame thickness in outline mode.</p>

<i>lThick=l</i>	Sets line thickness in points (default is 0.5 for $l=0$ ).
<i>lineRGB=(r,g,b)</i>	Sets color for lines. Default is all zeros (black); the same as the tag frame.
<i>dash=d</i>	Specifies dash pattern number between 0 and 17 (see <b>SetDashPattern</b> for patterns).
<i>/W=winName</i>	Operates on the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy.
<i>/V=vis</i>	<i>vis=0</i> : Invisible annotation; not selectable. The annotation is still listed in <b>AnnotationList</b> . <i>vis=1</i> : Visible annotation (default).
<i>/X=xOffset</i>	Distance from point to tag as percentage of graph width. For axis tags, the offsets are proportional to the size of the text used for the axis labels.
<i>/Y=yOffset</i>	Distance from point to tag as percentage of graph height. For axis tags, the offsets are proportional to the size of the text used for the axis labels.
<i>/Z=freeZe</i>	<i>freeZe=1</i> : Freezes tag position (you can't move it with the mouse). <i>freeZe=0</i> : Unfreezes it.

## Details

If the */C* flag is used, it must be the first flag in the command and must be followed immediately by the */N=name* flag.

If the */K* flag is used, it must be the first flag in the command and must be followed immediately by the */N=name* flag with no further flags or parameters.

*traceOrAxisName*, *xAttach*, and *textStr* are all optional. If *traceOrAxisName* is specified, then *xAttach* must be specified, and vice versa. *textStr* may be specified only if *traceOrAxisName* and *xAttach* are specified.

This syntax allows changes to the tag to be made through the *flags* parameters without needing to respecify the other parameters. Similarly, the tag's attachment point can be changed without needing to respecify the *textStr* parameter.

*xAttach* is in terms of the wave's X scaling. If *traceOrAxisName* is displayed as an XY pair, we recommend that you use "point scaling" for the waves, so that *xAttach* can be a point number (because *xAttach* will not be an X axis value).

A tag can have at most 100 lines.

*textStr* can contain the following escape codes which affect subsequent characters in string.

**Note:** These escape codes contain backslashes, which should themselves be preceded with another backslash. These are automatically inserted by the Add Annotation dialog, but must be manually added when writing a function or in the command line. See the discussion in the **TextBox** operation about backslashes in *textStr*.

The characters "<?>" in a tag indicate that you specified an invalid escape code or used a font that is not available.

The escape codes are:

<i>\B</i>	Use subscript (smaller type).
<i>\F'fontName'</i>	Use specified font (e.g., <i>\F 'Helvetica'</i> ).
<i>\fdd</i>	<i>dd</i> is a binary coded number with each bit controlling one aspect of the column's font style as follows: bit 0: Bold. bit 1: Italic. bit 2: Underline. bit 3: Outline ( <i>Macintosh only</i> ). bit 4: Shadow ( <i>Macintosh only</i> ).

For example, bold underline is  $2^0 + 2^2 = 1 + 4 = 5$ . See **Setting Bit Parameters** on page IV-11 for details about bit settings.

---

<code>\JR</code>	Right aligned text.
<code>\JC</code>	Center aligned text.
<code>\JL</code>	Left aligned text.
<code>\K(<i>r,g,b</i>)</code>	Use specified color for text. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535.
<code>\M</code>	Use normal (main) script (reverts to main line and size).
<code>\S</code>	Use superscript (uses smaller type).
<code>\Znn</code>	Use font size <i>nn</i> ( <i>nn</i> must be exactly two digits).
<code>\Zrnnn</code>	<i>nnn</i> is a 3 digit percentage by which to change the current font size. ( <i>nnn</i> must be exactly three digits).

*textStr* can also contain escape codes to manipulate text info variables (see **About Text Info Variables** on page III-61).

When specifying an axis tag, you can also use additional dynamic escape codes that are available with the **Label** operation.

*textStr* can also contain the following escape codes which insert dynamically computed substrings:

<code>\ON</code>	Inserts name of wave to which tag is attached.
<code>\On</code>	Inserts name of wave and its instance number (if greater than 0).
<code>\OP</code>	Inserts point number to which tag is attached.
<code>\OX</code>	Inserts X value of point to which tag is attached ( <i>xAttach</i> ).
<code>\OY</code>	Inserts Y value of point to which tag is attached.
<code>\OZ</code>	Inserts Z value of point to which tag is attached for contour level traces. Inserts NaN for other traces.
<code>\{<i>dynText</i>\}</code>	<i>dynText</i> is dynamically evaluated text, which is discussed below.

Dynamically evaluated text (*dynText*) may contain numeric and string expressions. Igor automatically reevaluates *dynText* when a numeric or string variable or wave referenced in *dynText* changes.

**Note:** When used in *dynText* expressions, user-defined numeric and string variables in macros or functions must be declared as global variables for the expression to evaluate correctly.

*dynText* can take two forms, an easy one for a single numeric expression and a more complex form that provides precise control over the formatting of the result.

The easy form is:

```
\{numeric-expression\}
```

This evaluates the expression and prints with generic ("%g") formatting.

The full form is:

```
\{formatStr, list-of-numeric-or-string-expressions\}
```

*formatStr* and *list-of-numeric-or-string-expressions* are treated as for **printf**.

As an aid in typing the expressions, Igor considers carriage returns between the braces to be equivalent to spaces. Rather than typing (in the Add Annotation dialog):

```
\{"twice K0 is %g, and today is %s",2*K0,date() }
```

you can type:

```
\{
  "twice K0 is %g, and today is %s",
  2*K0,
  date()
}
```

Carriage returns can be typed directly in the Add Annotations dialog, or they can be typed as "\r" in a macro, function or the command line. Since \r is not a tag escape sequence, only one backslash is needed. See the examples.

### Examples

```
Tag/C/N=t1/X=25/Y=50
```

moves the tag named t1 to the location defined by X=25 and Y=50.

```
Tag/C/N=t1 wave1, 50
```

## TagVal

moves the tag named t1 to wave1 at x=50.

```
Tag/N=t2 wave1, 50, "\\JC\\{numpts(wave1)} points\\rin this wave"
```

creates a new tag on wave1 that looks like this:

128 points  
in this wave

```
Tag w,0, "\\{"%g is first, %g is last\\"rw[0],w[numpts(w)-1]}"
```

creates a new tag on w that looks like this:

0 is first, 31.75 is last

Observe how the "\r" in the *textStr* breaks the annotation text by examining the Modify Annotation dialog:

Following is an example of various ways in which axis tags can be used:

```
Make/O jack=sin(x/8)
SetScale x,0,14e9,"y" jack
Display jack
Label bottom "\\u#2" // turn off default axis label
ModifyGraph axOffset(bottom)=1.16667 // make room for tag (manual adjustment)
Tag/N=text0/F=0/A=MT/X=0.20/Y=-4.29/L=0 bottom, Nan, "\\JCTime (\\U)rGratuitous 2nd line"

// now a few "important location" tags...
Tag/N=text1/F=0/A=LB/X=1.20/Y=3.00 bottom, 0, "Big Bang"
Tag/N=text2/F=0/A=MB/X=0.00/Y=2.86 bottom, 8000000000, "Earth formed"
Tag/N=text3/F=0/A=RB/X=-0.80/Y=4.71 bottom, 13040000000, "Dinosaurs ruled"
```

## TagVal

### TagVal (code)

TagVal is a very specialized function that is only valid when called from within the text of a tag as part of a \{} dynamic text escape sequence. It returns a number reflecting some property of the tag and helps you to display information about the tagged wave. The property is selected by the *code* parameter:

<i>code</i>	Return Value
0	Similar to \OP, returns the tag attach point number.
1	Similar to \OX, returns the X coordinate of tag attachment in the graph. When a tag is attached to an XY pair of traces, the X coordinate will most likely be different than the tag's X scaling attachment value specified in the Tag command.
2	Similar to \OY, returns the Y coordinate of tag attachment in the graph or the Y axis value in a Waterfall plot.
3	Similar to \OZ, returns the Z coordinate of tag attachment in a contour, image, or Waterfall plot.
4	Similar to \Ox, returns the trace x offset.

<i>code</i>	<b>Return Value</b>
5	Similar to \Oy, returns the trace y offset.
6	Returns the X muloffset (with the not set value 0 translated to 1).
7	Returns the Y muloffset (with the not set value 0 translated to 1).

Because TagVal returns a numeric value, the result can be formatted any way you wish using the **printf** formatting codes. In contrast, the \O codes insert preformatted text, and you don't have control over the format.

TagVal is sometimes used in conjunction with the **TagWaveRef** function. For example, you might write a user-defined function that calculates a value as a function of a wave and a point number.

#### Examples

```
Tag wave0, 0, "Y value is \\{"%g\\",TagVal(2)}"
Tag wave0, 0, "Y value is \\{"%g\\",TagWaveRef()[TagVal(0)]}"
Tag wave0, 0, "Y value is \\OY"
```

These examples all produce identical results.

#### See Also

The **Tag** operation, the **TagWaveRef** function.

For a discussion of wave references, see **Wave Reference Functions** on page IV-143.

## TagWaveRef

### TagWaveRef()

TagWaveRef is a very specialized function that is only valid when called from within the text of a tag as part of a \{} dynamic text escape sequence. It returns a wave reference to the wave that the tag is on and helps you to display information about the tagged wave. It is often used in conjunction with the **TagVal** function. You can pass the result of TagWaveRef to any function that takes a Wave parameter.

#### Examples

Show the name of the data folder containing the tagged wave:

```
Tag wave0, 0, "\\ON is in \\{"%s\\",GetWavesDataFolder(TagWaveRef(),0)}"
```

#### See Also

The **Tag** operation, the **TagVal** function

For a discussion of wave references, see **Wave Reference Functions** on page IV-143.

## tan

### tan(*angle*)

The tan function returns the tangent of *angle* which is in radians. In complex expressions, *num* is complex, and tan(*num*) returns a complex value.

## tanh

### tanh(*num*)

The tanh function returns the hyperbolic tangent of *num*. In complex expressions, *num* is complex, and tanh(*num*) returns a complex value.

## TextBox

### TextBox [*flags*] [*textStr*]

The TextBox operation puts a textbox on the target or named graph window. A textbox is an annotation that is not associated with any particular trace.

#### Parameters

*textStr* is the text that is to appear in the textbox. It is optional.

#### Flags

/A=*anchorCode* Specifies position of textbox anchor point.

<i>anchorCode</i>	Position	<i>anchorCode</i>	Position
LT	left top	RT	right top
LC	left center	RC	right center
LB	left bottom	RB	right bottom
MT	middle top		
MC	middle center		
MB	middle bottom		

*anchorCode* is a literal, *not* a string.

For interior textboxes, the anchor point is on the rectangular edge of the plot area of the graph window (where the left, bottom, right, and top axes are drawn).

For exterior textboxes, the anchor point is on the rectangular edge of the entire graph window.

<i>/B=(r,g,b)</i>	Sets the color of the tag's background. <i>r</i> , <i>g</i> , and <i>b</i> specify the amount of red, green, and blue as an integer from 0 to 65535.
<i>/B=b</i>	<p><i>b=0</i>: Opaque background.</p> <p><i>b=1</i>: Transparent background.</p> <p><i>b=2</i>: Same background as the graph's plot area background.</p> <p><i>b=3</i>: Same background as the window background.</p>
<i>/C</i>	Changes existing textbox.
<i>/D={thickMult [, shadowThick [, haloThick]]}</i>	<p><i>thickMult</i> multiplies the normal frame thickness of a text-box. The thickness may be set using just <i>/D=thickMult</i>.</p> <p><i>shadowThick</i>, if present, overrides Igor's normal shadow thickness. It is in units of fractional points.</p> <p><i>haloThick</i> governs the annotation's halo thickness (a surrounding band of the annotation's background color), which can be -1 to 10 points wide.</p> <p>The default <i>haloThick</i> value is -1, which preserves the behavior of previous versions of Igor where the halo of all annotations was set by the global variable <code>root:V_TBBufZone</code>. Any negative value of <i>haloThick</i> (-0.5, for example) will be overridden by <code>V_TBBufZone</code> if it exists, otherwise the absolute value of <i>haloThick</i> will be used. A zero or positive value overrides <code>V_TBBufZone</code>.</p> <p>Any of the parameters may be missing. To set <i>haloThick</i> to 0 without changing other parameters, use <i>/D={, , 0}</i>.</p>
<i>/E[=exterior]</i>	<p><i>/E</i> or <i>/E=1</i> forces textbox (or legend) to be exterior to graph (provided <i>anchorCode</i> is not MC) and pushes the graph margins away from the anchor edge(s). <i>/E=2</i> also forces exterior mode but does not push the margins.</p> <p><i>/E=0</i> returns it to the default (an "interior textbox" which can be anywhere in the graph window).</p>
<i>/F=frame</i>	<p><i>frame=0</i>: No frame.</p> <p><i>frame=1</i>: Underline frame.</p> <p><i>frame=2</i>: Box frame (default).</p>
<i>/G=(r,g,b)</i>	Sets color of the text in the tag. <i>r</i> , <i>g</i> , and <i>b</i> specify the amount of red, green, and blue as an integer from 0 to 65535.
<i>/H=legendSymbolWidth</i>	<i>legendSymbolWidth</i> sets width of the legend symbol (the sample line or marker) in points. Use 0 for the default, automatic width.
<i>/K</i>	Kills existing textbox.
<i>/LS= linespace</i>	Specifies a tweak to the normal line spacing where <i>linespace</i> is points of extra (plus or minus) line spacing. For negative values, a blank line may be necessary to avoid clipping the bottom of the last line.

<i>/M[=sameSize]</i>	<i>/M</i> or <i>/M=1</i> specifies that legend markers should be the same size as the marker in the graph. <i>/M=0</i> turns same-size mode off so that the size of the marker in the legend is based on text size.
<i>/N=name</i>	Specifies the name of the textbox to change or create.
<i>/O=rot</i>	Rotates the text by <i>rot</i> degrees counterclockwise (valid rotations are -90, 0, 90, 180, or 270). 0 is normal horizontal left-to-right text. 90 is vertical bottom-to-top text, etc.
<i>/R=newName</i>	Renames the textbox.
<i>/S=style</i>	<i>style=0</i> : Single frame. <i>style=1</i> : Double frame. <i>style=2</i> : Triple frame. <i>style=3</i> : Shadow frame.
<i>/T=tabSpec</i>	<i>tabSpec</i> is a single number in points, such as <i>/T=72</i> , for evenly spaced tabs or a list of tab stops in points such as <i>/T={50, 150, 225}</i> .
<i>/V=vis</i>	<i>vis =0</i> : Invisible annotation; not selectable. The annotation is still listed in <b>AnnotationList</b> . <i>vis =1</i> : Visible annotation.
<i>/W=winName</i>	Operates in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy.
<i>/X=xOffset</i>	For interior textboxes <i>xOffset</i> is the distance from anchor to textbox as a percentage of the plot area width. For exterior textboxes <i>xOffset</i> is the distance from anchor to textbox as a percentage of the graph window width. See <i>/E</i> and <i>/A</i> .
<i>/Y=yOffset</i>	<i>yOffset</i> is the distance from anchor to textbox as a percentage of the plot area height (interior textboxes) or graph window height (exterior textboxes). See <i>/E</i> and <i>/A</i> .
<i>/Z=freeze</i>	<i>freeze=1</i> : Freezes annotation position (you can't move it with the mouse) in graphs but not in page layouts. <i>freeze=0</i> : Unfreezes it. Annotations are always unfrozen in page layouts.

### Details

Use the optional */W=winName* flag to specify a specific graph or layout window. When used on the command line or in a Macro, Proc, or Window procedure, */W* must precede all other flags.

If the */C* flag is used, it must be the first flag in the command (except that it may follow an initial */W*) and must be followed immediately by the */N=name* flag.

If the */K* flag is used, it must be the first flag in the command (or follow an initial */W*) and must be followed immediately by the */N=name* flag with no further flags or parameters.

*textStr* is optional. If missing, the textbox text is unchanged. This allows changes to the textbox to be made through the flags without changing the text.

A textbox can have at most 100 lines.

*textStr* can contain the following escape codes which affect subsequent characters in string. See **Notes about Backslashes**.

The characters "<??>" in a textbox indicate that you specified an invalid escape code or used a font that is not available.

The escape codes are:

<i>\[&lt;digit&gt;</i>	Store info variable.
<i>\]&lt;digit&gt;</i>	Recall info variable.
<i>\B</i>	Use subscript (in smaller type above baseline).
<i>\F'fontName'</i>	Use specified font (e.g., <i>\F 'Helvetica'</i> ).

## TextBox

---

<code>\fdd</code>	<p><i>dd</i> is a binary coded number with each bit controlling one aspect of the column's font style as follows:</p> <ul style="list-style-type: none"><li>bit 0: Bold</li><li>bit 1: Italic</li><li>bit 2: Underline</li><li>bit 3: Outline (<i>Macintosh only</i>)</li><li>bit 4: Shadow (<i>Macintosh only</i>)</li></ul> <p>For example, bold underline is <math>2^0 + 2^2 = 1 + 4 = 5</math>. See <b>Setting Bit Parameters</b> on page IV-11 for details about bit settings.</p>
<code>\JR</code>	Right align text.
<code>\JC</code>	Center align text.
<code>\JL</code>	Left align text.
<code>\K(r,g,b)</code>	Use specified color for text. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535.
<code>\k(r,g,b)</code>	Use specified color for marker stroke (line color). <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535. Use before <code>\Wtdd</code> to change marker stroke color from the default of black (0,0,0).
<code>\Ldtss</code>	Draws a line from x position specified in text info variable <i>d</i> to the current x position. Uses current text color. Thickness is encoded by digit <i>t</i> with values of 4,5,6 and 7 giving 0.25, 0.5, 1.0 and 1.5 pt. Line style is specified by 2 digit number <i>ss</i> .
<code>\M</code>	Use normal (main) script (reverts to main line and size).
<code>\S</code>	Use superscript (in smaller type below baseline).
<code>\Wtdd</code>	Draws a marker symbol using current font size and color. Line thickness is coded by digit <i>t</i> with 4, 5 and 6 giving 0.25, 0.5 and 1.0 pt. Marker symbol number is specified by 2 digit number <i>dd</i> .
<code>\X&lt;digit&gt;</code>	Recall X position.
<code>\x+dd</code>	Moves X position right by $2*dd$ percent of the current font max width.
<code>\x-dd</code>	Moves X position left by $2*dd$ percent of the current font max width.
<code>\Y&lt;digit&gt;</code>	Recall Y position.
<code>\y+dd</code>	Moves Y position up by $2*dd$ percent of the current font height.
<code>\y-dd</code>	Moves Y position down by $2*dd$ percent of the current font height.
<code>\Znn</code>	Use font size <i>nn</i> ( <i>nn</i> must be exactly two digits).
<code>\Zrnnn</code>	<i>nnn</i> is a 3 digit percentage by which to change the current font size. ( <i>nnn</i> must be exactly three digits).

*textStr* can also contain escape codes to manipulate text info variables (see **About Text Info Variables** on page III-61).

*textStr* can also contain the following escape code which inserts the symbol used to display the named wave:

`\s( traceName)`

`\s` is mainly used in Legends, where legend symbols are automatically created and removed, but it can also be used in Tags, Textboxes, and axis labels where the symbol is updated, but not automatically added or removed. See **Freezing the Legend Text** on page III-50.

*textStr* can also contain an escape code which inserts dynamically evaluated text:

`\{dynText}`

Dynamically evaluated text (*dynText*) may contain numeric and string expressions. Igor automatically reevaluates *dynText* when a numeric or string variable or wave referenced in *dynText* changes.

**Note:** When used in *dynText* expressions, user-defined numeric and string variables in macros or functions must be declared as global variables for the expression to evaluate correctly.

*dynText* can take two forms, an easy one for a single numeric expression and a more complex form that provides precise control over the formatting of the result.

The easy form is:

`\{numeric-expression}`

This evaluates the expression and prints with generic ("%g") formatting.

The full form is:

```
\{formatStr, list-of-numeric-or-string-expressions}
```

*formatStr* and *list-of-numeric-or-string-expressions* are treated as for **printf**.

As an aid in typing the expressions, Igor considers carriage returns between the braces to be equivalent to spaces. Rather than typing (in the Add Annotation dialog):

```
\{"twice K0 is %g, and today is %s",2*K0,date() }
```

you can type:

```
\{
    "twice K0 is %g, and today is %s",
    2*K0,
    date()
}
```

These carriage returns can be typed directly in the Add Annotations dialog, or be typed as “\r” in a macro, function or the command line.

### Notes about Backslashes

Each backslash character in *textStr* should be preceded with another backslash when it appears in a macro, function or on the command line. This is because backslash is itself a special escape character for strings. Future versions of Igor may require this double-backslash syntax; currently Igor accepts either the single or double backslash as synonyms for inserting a single backslash into a string.

For example:

```
String myStr = "\\OK"
Print myStr
```

Prints the following in the history area:

```
\OK
```

*myStr* contains a *single* backslash character. See **Escape Characters in Strings** on page IV-13 for more about the backslash character. This behavior affects how escape sequences in *textStr* should be written:

```
TextBox/C/N=text0 "\Z14Bigger" // no: Future Igors may see "Z14Bigger"
TextBox/C/N=text0 "\\Z14Bigger" // yes
TextBox/C/N=text0 "first line\rsecond line" // carriage return uses one \
```

Since \r (carriage return) is not a textbox escape sequence, only one backslash is needed.

You can see how backslashes in *textStr* should be entered by using the Add Annotation dialog and observing the command it creates. You will observe many double backslash sequences. Single backslash sequences were used by Igor 1.2, which Igor Pro currently accepts for backward compatibility reasons.

### Examples

```
TextBox/C/N=t1/X=25/Y=50
```

moves the textbox named t1 to the location defined by X=25 and Y=50.

```
TextBox/C/N=t1 "New Text"
```

changes the text for t1.

### See Also

See **About Text Info Variables** on page III-61 for *textStr* escape codes that manipulate text info variables. The **AppendText** operation. See the discussion above in **Notes about Backslashes and Escape Characters in Strings** on page IV-13 for still more about the backslash character. See the **printf** operation for formatting codes used in *formatStr*.

## TextFile

```
TextFile(pathName, index [, creatorStr])
```

The **TextFile** function returns a string containing the name of the *index*th TEXT file from the folder specified by *pathName*.

On Windows, Igor considers files with “.txt” extensions to be of type TEXT.

### Details

**TextFile** returns the null string (“”) if there is no such file.

*pathName* is the name of an Igor symbolic path; it is *not* a string.

## ThreadGroupCreate

---

*index* starts from zero.

*creatorStr* is an optional string argument containing four characters such as "IGR0". Only files of the specified Macintosh creator code are indexed. Set *creatorStr* to "?????" to index all text files (or omit the argument altogether). This argument is ignored on Windows systems.

The order of files in a folder is determined by the operating system.

### Examples

You can use `TextFile` in a procedure to sequence through each TEXT file in a folder, put the name of the text file into a string variable, and use this string variable as a parameter to the **LoadWave** or **Open** operations:

```
Function/S PrintFirstLineOfTextFiles(pathName)
  String pathName                // Name of an Igor symbolic path.
  Variable refNum, index
  String str, fileName
  index = 0
  do
    fileName = TextFile($pathName, index)
    if (strlen(fileName) == 0)
      break                      // No more files
    endif
    Open/R/P=$pathName refNum as fileName
    FReadLine refNum, str        // Read first line including CR/LF
    Print fileName + ":" + str   // Print file name and first line
    Close refNum
    index += 1                  // Next file
  while (1)
End
```

### See Also

See the **IndexedFile** function, which is similar to `TextFile` but works on files of any type, and also **IndexedDir**. Also see the **LoadWave** and **Open** the operations.

## ThreadGroupCreate

### **ThreadGroupCreate**(*nt*)

The `ThreadGroupCreate` function creates a thread group containing *nt* threads and returns a thread ID number. Use the number of computer processors for *nt* when trying to improve computation speed using parallel threads. A background worker might use just one thread regardless of the number of processors.

### See Also

**ThreadSafe Functions** on page IV-66 and **ThreadSafe Functions and Multitasking** on page IV-214.

## ThreadGroupGetDF

### **ThreadGroupGetDF**(*tgID*, *waitms*)

The `ThreadGroupGetDF` string function retrieves a data folder from a thread group input queue when called from a preemptive thread or, when called from the main thread, retrieves data folder of data from the thread group's output queue. Returns the data folder name or "" if none found owing to timeout. *tgID* is the thread group ID returned by **ThreadGroupCreate**, *waitms* is milliseconds to wait. When called from a preemptive thread, *tgID* may be zero.

Considerations for milliseconds to wait are the same as those for **ThreadGroupWait**.

### See Also

**ThreadSafe Functions** on page IV-66 and **ThreadSafe Functions and Multitasking** on page IV-214.

## ThreadGroupPutDF

### **ThreadGroupPutDF** *tgID*, *datafolder*

The `ThreadGroupPutDF` operation posts data to a preemptive thread group.

### Parameters

*tgID* is thread group ID returned by **ThreadGroupCreate**, *datafolder* is the data folder you wish to send to the thread group.

*datafolder* can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

**Details**

When called from the main thread, **ThreadGroupPutDF** removes *datafolder* from main and posts to the input queue of the thread group specified by *tgID*. When called from a preemptive thread, use 0 for *tgID* and the data folder will be posted to the output queue of thread group to which thread belongs. Input and output data folders may be retrieved from the queues by calling the string function **ThreadGroupGetDF**.

**Warning:** Take care not to use any stale WAVE, NVAR, or SVAR variables that might contain references to objects in the data folder. Use **WAVEClear** on all WAVE reference variables that might contain references to waves that are in the data folder being posted before calling **ThreadGroupPutDF**. An error will occur if any waves in the data folder are in use or referenced in a WAVE variable.

From the standpoint of the source thread, **ThreadGroupPutDF** is conceptually similar to **KillDataFolder** and, like **KillDataFolder**, if the current data folder is within *datafolder*, the current data folder is set to the parent of *datafolder*. You can not pass `root : as datafolder`.

**See Also**

The **ThreadGroupCreate** function, **ThreadSafe Functions** on page IV-66, and **ThreadSafe Functions and Multitasking** on page IV-214.

## ThreadGroupRelease

**ThreadGroupRelease ( *tgID* )**

The **ThreadGroupRelease** function releases thread group (and *tgID* is no longer valid). *tgID* is the thread group ID returned by **ThreadGroupCreate**.

If threads are still running, they are killed. An attempt is made to safely stop running threads but, if they continue to run, they will be force quit.

**ThreadGroupRelease** returns zero if successful, -1 if an error occurred (probably invalid *tgID*), or -2 if a force quit was needed. In the latter case, you should restart Igor Pro.

Any data folders remaining in the group's input or output queues will be discarded.

**See Also**

The **ThreadGroupCreate** function, **ThreadSafe Functions** on page IV-66, and **ThreadSafe Functions and Multitasking** on page IV-214.

## ThreadGroupWait

**ThreadGroupWait ( *tgID*, *waitms* )**

The **ThreadGroupWait** function returns index+1 of the first thread found still running after *waitms* or returns zero if all are done. *tgID* is the thread group ID returned by **ThreadGroupCreate** and *waitms* is milliseconds to wait.

If any of the threads of the group encountered a runtime error, the first such error will be reported now.

Use zero for milliseconds to wait to just test or provide a large value to cause the main thread to sleep until the threads are finished. You can use `inf` to wait forever (or until a user abort.) If you know the maximum time the threads should take, you can use that value so you can print an error message or take other action if the threads don't return in time.

**See Also**

The **ThreadGroupCreate** function, **ThreadSafe Functions** on page IV-66, and **ThreadSafe Functions and Multitasking** on page IV-214.

## ThreadProcessorCount

**ThreadProcessorCount**

The **ThreadProcessorCount** function returns the number of processors in your computer. For example, on a Macintosh Core Duo, it would return 2.

## ThreadReturnValue

---

### ThreadReturnValue

#### **ThreadReturnValue**(*tgID*, *index*)

The ThreadReturnValue function returns the value that the specified thread function returned when it exited. Returns NAN if thread is still running. *tgID* is the thread group ID returned by **ThreadGroupCreate**) and *index* is the thread number.

#### See Also

The **ThreadGroupCreate** function, **ThreadSafe Functions** on page IV-66, and **ThreadSafe Functions and Multitasking** on page IV-214.

### ThreadSafe

#### **ThreadSafe Function** *funcName*()

The ThreadSafe keyword declaration specifies that a user function can be used for preemptive multitasking background tasks on multiprocessor computer systems.

A ThreadSafe function is one that can operate correctly during simultaneous execution by multiple threads. Such functions are generally limited to numeric or utility functions. Functions that access windows are not ThreadSafe. To determine if an operation is ThreadSafe, use the Command Help tab of the Help Browser and choose ThreadSafe from the pop-up menu.

ThreadSafe functions can call other ThreadSafe functions but may not call non-ThreadSafe functions. Non-ThreadSafe functions can call ThreadSafe functions.

#### See Also

**ThreadSafe Functions** on page IV-66 and **ThreadSafe Functions and Multitasking** on page IV-214.

### ThreadStart

#### **ThreadStart** *tgID*, *index*, *WorkerFunc*(*param1*, *param2*,...)

The ThreadStart operation starts the specified function running in a preemptive thread.

#### Parameters

*tgID* is thread group ID returned by **ThreadGroupCreate**, *index* is the desired thread of the group to set up to execute the specified ThreadSafe *WorkerFunc*.

#### Details

Your function starts running immediately.

You may not use any pass-by-reference parameters. Any waves you pass are then accessible to both the main thread and to your preemptive thread. Such waves are then marked as being in use by a thread and Igor will refuse to perform any manipulations that could change the size of the wave.

The function must be defined as ThreadSafe and be numeric, either real or complex. The return value can be obtained after the function finishes by calling ThreadReturnValue.

#### See Also

The **ThreadGroupCreate** and **ThreadReturnValue** functions; **ThreadSafe Functions** on page IV-66, and **ThreadSafe Functions and Multitasking** on page IV-214.

### ticks

#### **ticks**

The ticks function returns the number of ticks (approximately 1/60 second) elapsed since the operating system was initialized.

#### See Also

The **stopMSTimer** function.

## Tile

**Tile** [*flags*] [*objectName* [, *objectName*]...]

The Tile operation tiles the specified objects in the top page layout.

### Parameters

*objectName* is the name of a graph, table, picture or annotation object in the top page layout.

### Flags

<i>/A=(rows,cols)</i>	Specifies number of rows/columns in which to tile objects.
<i>/G=grout</i>	Specifies grout, the spacing between window tiles, in prevailing coordinates (points unless preceded by <i>/I</i> , <i>/M</i> or <i>/R</i> ).
<i>/I</i>	Specifies coordinates in inches.
<i>/M</i>	Specifies coordinates in centimeters.
<i>/O=objTypes</i>	Adds objects of type(s) specified by bitwise mask to list of objects to be tiled: 1 (bit 0): Tile graphs. 2 (bit 1): Tile tables. 8 (bit 3): Tile pictures. 32 (bit 5): Tile textboxes. See <b>Setting Bit Parameters</b> on page IV-11 for details about bit settings.
<i>/R</i>	Specifies coordinates measured in percent of the printable page.
<i>/S</i>	Adds selected objects to objects to be tiled.
<i>/W=(left,top,right,bottom)</i>	Specifies page layout area in which to tile objects. Coordinates are in points unless <i>/I</i> , <i>/M</i> or <i>/R</i> are specified before <i>/W</i> .

### Details

If */A=(rows,cols)* is not used, Tile uses an appropriate number of rows and columns. If */A=(rows,cols)* is used, objects are tiled in a grid of that many rows and columns. If *rows* or *cols* is zero, it substitutes an appropriate number for the zero parameter.

Objects to be tiled are determined by the */S* and */O=objTypes* flags and by any *objectNames*.

If no */S* or */O* flags are present and there are no *objectNames*, then all objects in the layout are tiled.

Otherwise the objects to be tiled are determined as follows:

- All *objectNames* are tiled.
- If the */S* flag is present, the selected objects (if any) are also tiled.
- If the */O=objTypes* flag is present then any objects specified by *objTypes* are also tiled. *objTypes* is a bitwise mask, so */O=3* tiles both graphs and tables.

### See Also

The **Stack** operation.

## TileWindows

**TileWindows** [*flags*] [*windowName* [, *windowName*]...]

The TileWindows operation tiles the specified windows on the desktop (*Macintosh*) or in the Igor frame window (*Windows*).

### Flags

<i>/A=(rows,cols)</i>	Specifies number of rows/columns in which to tile windows.
<i>/C</i>	Adds the command window to the windows to be tiled.
<i>/G=grout</i>	Specifies grout, the spacing between tiles, in prevailing units (points unless <i>/I</i> or <i>/M</i> are used).
<i>/I</i>	Specifies coordinates in inches.
<i>/M</i>	Specifies coordinates in centimeters.
<i>/O=objTypes</i>	Adds windows of types specified by <i>objTypes</i> to windows to be tiled. <i>objTypes</i> is a bitwise mask where: bit 0: Graphs.

## time

---

- bit 1: Tables.
- bit 2: Page layouts.
- bit 4: Notebooks.
- bit 6: Control panels.
- bit 7: Procedure windows.
- bit 9: Help windows.
- bit 12: XOP target windows (e.g., surface plots).

Other bits should always be zero. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

*/P* Adds the main procedure window to the windows to be tiled.

*/R* Specifies coordinates measured as % of tiling rectangle.

*/W=(left,top,right,bottom)*

Specifies tiling rectangle on the screen. Coordinates are in points unless */I*, */M*, or */R* are specified before */W*.

### Details

The windows to be tiled are determined by the */C*, */P*, and */O=objTypes* flags and by the *windowNames*. If no */C*, */P* or */O* flags are present and there is no *windowNames* then all windows are tiled.

Otherwise the windows to be tiled are determined as follows:

- All named windows are tiled.
- If the */C* flag is present, the command window is also tiled.
- If the */P* flag is present, the procedure window is also tiled.
- If the */O=objTypes* flag is present, any windows specified by *objTypes* are also tiled.

### Examples

To tile all the procedure windows, including the main one, use:

```
TileWindows/P/O=128 // 2^7=128
```

### See Also

The **StackWindows** operation.

## time

### **time()**

The time function returns a string containing the current time. The empty parentheses are required.

### See Also

The **date**, **date2secs** and **DateTime** functions.

## TitleBox

**TitleBox** [*/Z*] *ctrlName* [*key* [= *value*]][, *key* [= *value*]]...

The TitleBox operation creates the named title box in the target window.

For information about the state or status of the control, use the **ControlInfo** operation.

### Parameters

*ctrlName* is the name of the TitleBox control to be created or changed.

*key* is one of the following parameters:

*anchor= hv* Specifies the anchor mode using a two letter code, *hv*. *h* may be L, M, or R for left, middle, and right. *v* may be T, C, or B for top, center and bottom. Default is LT.

*appearance={kind [, platform]}*

Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

*kind* can be one of **default**, **native**, or **os9**.

*platform* can be one of **Mac**, **Win**, or **All**.

See **Button** and **DefaultGuiControls** for more appearance details.

<code>disable=<i>d</i></code>	Sets user editability of the control. <code>d=0:</code> Normal. <code>d=1:</code> Hide. <code>d=2:</code> Draw in gray state.
<code>fColor=(<i>r,g,b</i>)</code>	Sets color of the titlebox. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535
<code>font="fontName"</code>	Sets the font used for the control, e.g., <code>font="Helvetica"</code> .
<code>frame=<i>f</i></code>	Sets frame style. <code>f=0:</code> No frame. <code>f=1:</code> Default (same as <code>f=3</code> ). <code>f=2:</code> Simple box. <code>f=3:</code> 3D sunken frame. <code>f=4:</code> 3D raised frame. <code>f=5:</code> Text well.
<code>fsize=<i>s</i></code>	Sets font size.
<code>fstyle=<i>fs</i></code>	<i>fs</i> is a binary coded number with each bit controlling one aspect of the font style as follows: bit 0: Bold. bit 1: Italic. bit 2: Underline. bit 3: Outline ( <i>Macintosh only</i> ). bit 4: Shadow ( <i>Macintosh only</i> ). See <b>Setting Bit Parameters</b> on page IV-11 for details about bit settings.
<code>labelBack=(<i>r,g,b</i>) or 0</code>	Sets background color for title box. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535. If not set (or <code>labelBack=0</code> ), then background is transparent (not erased).
<code>pos={<i>left,top</i>}</code>	Sets the location of the top left corner in pixels.
<code>size={<i>w,h</i>}</code>	Set the width and height in pixels.
<code>title=<i>titleStr</i></code>	Sets text of title box to <i>titleStr</i> . Limited to 63 characters.
<code>variable=<i>svar</i></code>	Specifies an optional global string variable from which to get the TitleBox text.
<code>win=<i>winName</i></code>	Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed. When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy.

**Flags**

`/Z` No error reporting.

**Details**

The text can come from either the `title=titleStr` or `variable=svar` method. Whichever is used last is the current method. The maximum length of text with the `title=titleStr` method is 63 chars while the `variable=svar` method has no limit.

The text can contain escape codes to create fancy results with multiple lines, font changes etc. The escape codes are essentially the same as those for the TextBox operation. The easiest way to generate fancy text is to create a dummy TextBox, set up the text as desired and then click the To Cmd Line button followed by editing of the command line.

The TitleBox automatically resizes itself relative to the anchor point on the rectangle that encloses the text. Therefore you can specify a size of 0,0 along with a pos value to place the anchor point at the pos value.

TitleBoxes can be used not only for titles but also as status or results readout areas, especially in conjunction with the `variable=svar` mode.

**Examples**

```
NewPanel /W=(94,72,459,294)
DrawLine 150,32,150,140
DrawLine 70,100,213,100 // draw crossing lines at 150,100
```

## ToCommandLine

---

```
// illustrate a default box
TitleBox tbl,title="A title box\rwith 2 lines",pos={150,100}

// Move center to 150,100
TitleBox tbl,pos={150,100},size={0,0},anchor=MC
// Set background color and therefore opaque mode
TitleBox tbl,labelBack=(55000,55000,65000)

// Now a few frame styles. Run these one at a time
TitleBox tbl,frame= 0 // no frame
TitleBox tbl,frame= 2 // plain frame
TitleBox tbl,frame= 3 // 3D sunken
TitleBox tbl,frame= 4 // 3D raised
TitleBox tbl,frame= 5 // text well

// Now some fancy text...
TitleBox tbl,frame= 1 // back to default (3D raised)
TitleBox tbl,title= "\Z18\[020 log\B10\M|[1 + 2K(jwt) + (jwt)\S2\M]|\S-1"

// Create a string variable and hook up to the TitleBox
String s1= "text from a string variable"
TitleBox tbl,variable=s1

// Change string variable contents & note automatic update of TitleBox
s1= "something new"
```

## ToCommandLine

### ToCommandLine *commandsStr*

The ToCommandLine operation sends command text to the command line without executing the command(s).

The intended usage is for user-created panel windows with “To Cmd Line” buttons that are mimicking built-in Igor dialogs. You’ll usually want to use Execute, instead.

### Parameters

*commandsStr*            The text of one or more commands.

### Details

To send more than one line of commands, separate the commands with “\r” characters.

**Note:**            ToCommandLine does not work when typed on the command line; use it only in a Macro, Proc, or Function.

### Examples

```
Macro CmdPanel()
  PauseUpdate; Silent 1
  NewPanel /W=(150,50,430,229)
  Button toCmdLine,pos={39,148},size={103,20},title="To Cmd Line"
  Button toCmdLine,proc=ToCmdLineButtonProc
End

Function ToCmdLineButtonProc(ctrlName) : ButtonControl
  String ctrlName
  String cmd="MyFunction(xin,yin,\"yResult\")" // line 1: generate results
  cmd += "\rDisplay yOutput vs wx as \"results\"" // line 2: display results
  ToCommandLine cmd
End
```

### See Also

The Execute and DoIgorMenu operations.

## ToolsGrid

**ToolsGrid** [/W=*winName*] **keyword** = **value** [, **keyword** = **value** ...]

The ToolsGrid operation controls the grid you can use for laying out draw or control objects.

### Parameters

ToolsGrid can accept multiple *keyword = value* parameters on one line.

<code>snap=<i>n</i></code>	Turns snap to grid on ( $n=1$ ) or off ( $n=0$ ).
<code>visible=<i>n</i></code>	Turns on grid visibility ( $n=1$ ) or hides it ( $n=0$ ).
<code>grid=(<i>xy0,dxy,ndiv</i>)</code>	Defines both X and Y grids where <i>ndiv</i> is the number of subdivisions between major grid lines and <i>xy0</i> and <i>dxy</i> define the origin and spacing. Units are in points.
<code>gridx=(<i>x0,dx,ndiv</i>)</code>	Defines the X grid where <i>ndiv</i> is the number of subdivisions between major grid lines and <i>x0</i> and <i>dx</i> define the origin and spacing. Units are in points.
<code>gridy=(<i>y0,dy,ndiv</i>)</code>	Defines the Y grid where <i>ndiv</i> is the number of subdivisions between major grid lines and <i>y0</i> and <i>dy</i> define the origin and spacing. Units are in points.

**Flags**

<code>/W=<i>winName</i></code>	Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.  When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy.
--------------------------------	---

**Details**

The default grid is 1 inch with 8 subdivisions. The grid is visible only in draw or selector mode and appears in front of the currently active draw layer.

## TraceFromPixel

**TraceFromPixel(*xpixel, ypixel, optionsString*)**

The TraceFromPixel function returns a string based on an attempt to hit test the provided X and Y coordinates. Used to determine if the mouse was clicked on a trace in a graph.

When a trace is found, TraceFromPixel returns a string containing the following **KEY:value;** pairs:

TRACE: *tracename*

HITPOINT: *pnt*

*tracename* will be quoted if necessary and may contain instance notation. *pnt* is the point number index into the trace's wave when the hit was detected. If a trace is not found near the coordinate point, a zero length string is returned.

**Parameters**

*xpixel* and *ypixel* are the X and Y pixel coordinates.

*optionsString* can contain the following:

WINDOW: *winName*;

PREF: *traceName*;

ONLY: *traceName*;

Use the WINDOW option to hit test in a graph other than the top graph. Use the ONLY option to search only for a special target trace. If the PREF option is used then the search will start with the specified trace but if no hit is detected, it will go on to the others.

When identifying a subwindow with WINDOW: *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**See Also**

The **NumberByKey**, **StringByKey**, **AxisValFromPixel**, and **PixelFromAxisVal** functions.

**ModifyGraph (traces)** and **Instance Notation** on page IV-16 for discussions of trace names and instance notation.

## TraceInfo

**TraceInfo(*graphNameStr, ywavenameStr, instance*)**

The TraceInfo function returns a string containing a semicolon-separated list of information about the trace in the named graph window or subwindow.

**Parameters**

*graphNameStr* can be "" to refer to the top graph.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

*yWaveNameStr* is either the name of a wave containing data displayed as a trace in the named graph, or a trace name (wave name with "#n" appended to distinguish the nth image of the wave in the graph). You might get a trace name from the **TraceNameList** function.

If *yWaveNameStr* contains a wave name, *instance* identifies which trace of *yWaveNameStr* you want information about. *instance* is usually 0 because there is normally only one instance of a given wave displayed in a graph. Set *instance* to 1 for information about the second trace of the wave named by *yWaveNameStr*, etc. If *yWaveNameStr* is "", then information is returned on the *instanceth* trace in the graph.

If *yWaveNameStr* is a trace name, and *instance* is zero, the instance is extracted from *yWaveNameStr*. If *instance* is greater than zero, the wave name is extracted from *yWaveNameStr*, and information is returned concerning the *instanceth* instance of the wave.

### Details

The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

Keyword	Information Following Keyword
AXISFLAGS	Flags used to specify the axes. Usually blank because /L and /B (left and bottom axes) are the defaults.
AXISZ	Z value of a contour level trace or NaN if the trace is not a contour trace.
RECREATION	List of keyword commands as used by ModifyGraph command. The format of these keyword commands is: <i>keyword(x)=modifyParameters;</i>
XAXIS	X axis name.
XRANGE	Point subrange of the trace's X data wave in "[startPoint, endPoint : increment]" format. <b>Note:</b> Unlike the actual syntax of a trace subrange specification where increment is preceded by a semicolon character, here it is preceded by a colon character to preserve the notion that semicolon is what separates the keyword-value groups. If the entire X wave is displayed (the usual case), the XRANGE value is "[*]". If an X wave is not used to display the trace, then the XRANGE value is "".
XWAVE	X wave name if any, else blank.
XWAVEDF	Full path to the data folder containing the X wave or blank if no X wave.
YAXIS	Y axis name.
YRANGE	Point subrange of the trace's Y data wave or "[*]".

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword and colon up to the ";", prepend "ModifyGraph ", replace the "x" with the name of a trace ("data#1" for instance) and then **Execute** the resultant string as a command.

**Note:** The syntax of any subrange specifications in the RECREATION information are modified in the same way as for XRANGE and YRANGE. Currently only the zColor, zmrkSize, and zmrkNum keywords might have a subrange specification.

### Examples

This example shows how to extract a string value from the keyword-value list returned by TraceInfo:

```
String yAxisName= StringByKey("YAXIS", TraceInfo("", "", 0))
```

This example shows how to extract a subrange and put the semicolon back:

```
String yRange= StringByKey("YRANGE", TraceInfo("", "", 0))
Print yRange // prints "[30,40:2]"
yRange= ReplaceString(":", yRange, ";")
Print yRange // prints "[30,40;2]"
```

The next example shows the trace information for the second instance of the wave "data" (which has an instance number of 1) displayed in the top graph:

```
Make/O data=x;Display/L/T data,data // two instances of data: 0 and 1
Print TraceInfo("", "data", 1)[0,64] // error if you try to print all
Print TraceInfo("", "data", 1)[65,128]
```

Prints the following in the history area:

```
XWAVE:;YAXIS:left;XAXIS:top;AXISFLAGS:/T;AXISZ:NAN(255);XWAVEDF:;
RECREATION:zColor(x)=0;zmrkSize(x)=0;zmrkNum(x)=0;textMarker(x)=
```

Following is a function that returns the marker code from the given instance of a named wave in the top graph. This example uses the convenient GetNumFromModifyStr() function provided by the #include <Readback ModifyStr> procedures, which are useful for parsing strings returned by TraceInfo.

```
#include <Readback ModifyStr>
Function MarkerOfWave(wv,instance)
    Wave wv
    Variable instance
    Variable marker
    String info = TraceInfo("",NameOfWave(wv),instance)
    marker = GetNumFromModifyStr(info,"marker","",0)
    return marker
End
```

**See Also**

The **Execute** operation.

## TraceNameList

**TraceNameList**(*graphNameStr*, *separatorStr*, *optionsFlag*)

The TraceNameList function returns a string containing a list of trace names in the graph window or subwindow identified by *graphNameStr*.

### Parameters

*graphNameStr* can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

The parameter *separatorStr* should contain a single character such as "," or ";" to separate the names.

### Details

The bits of *optionsFlag* have the following meanings:

Bit Number	Bit Value	Meaning
0	1	Include normal graph traces.
1	2	Include contour traces.

See **Setting Bit Parameters** on page IV-11 for details about bit settings.

A trace name is defined as the name of the Y wave that defines the trace with an optional #ddd suffix that distinguishes between two or more traces that have the same wave name. Since the trace name has to be parsed, it is quoted if necessary.

Commands that take a trace name as a parameter or in a keyword can use a string containing a trace name with the \$ operator to specify traceName. For instance, to change the display mode of a wave, you might use

```
ModifyGraph mode(myWave#1)=3
```

but

```
String myTraceName="myWave#1"
ModifyGraph mode($myTraceName)=3
```

will also work.

### Examples

```
Make jack,'jack # 2';Display jack,jack,'jack # 2','jack # 2'
Print TraceNameList("",";",1)
```

## TraceNameToWaveRef

---

prints jack;jack#1;'jack # 2';jack # 2'#1;

### See Also

For a description of traces: **ModifyGraph**. For a discussion of contour traces: **All About Contour Traces** on page II-306.

For commands referencing other waves in a graph: **ImageNameList**, **ImageNameToWaveRef**, **ContourNameList**, and **ContourNameToWaveRef**.

**ModifyGraph (traces)** and **Instance Notation** on page IV-16 for discussions of trace names and instance notation.

## TraceNameToWaveRef

**TraceNameToWaveRef**(*graphNameStr*, *traceNameStr*)

The **TraceNameToWaveRef** function returns a wave reference to the Y wave corresponding to the given trace in the graph window or subwindow named by *graphNameStr*.

### Parameters

*graphNameStr* can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

The trace is identified by the string in *traceNameStr*, which could be a string determined using **TraceNameList**. Note that the same trace name can refer to different waves in different graphs.

Use **Instance Notation** (see page IV-16) to choose from traces in a graph that represent waves of the same name. For example, if *traceNameStr* is "myWave#2", it refers to the third instance of wave "myWave" in the graph ("myWave#0" or just "myWave" is the first instance).

## Triangulate3d

**Triangulate3d** [/OUT=*format*] *srcWave*

The **Triangulate3d** operation creates a Delaunay "triangulation" of a 3D scatter wave. The output is a list of tetrahedra that completely span the convex volume defined by *srcWave*. **Triangulate3d** can also generate the triangulation needed for performing 3D interpolation for the same domain. Normally *srcWave* is a triplet wave (a 2D wave of 3 columns), but can use any 2D wave that has more than 3 columns (the operation ignores all but the first 3 columns).

### Flags

/OUT=*format* Specifies how to save the output triangulation data.

*format*=1: Default; saves the triangulation result in the wave **M\_3DVertexList**, which contains in each row, indices to rows in *srcWave* that describe the X, Y, Z coordinates of a single tetrahedral vertex. Each tetrahedron is described by one row in **M\_3DVertexList**.

*format*=2: Saves the triangulation result in the wave **M\_TetraPath**, which is a triplet path wave describing the tetrahedra edges. For each tetrahedron, there are four rows (triangles) separated by row of NaNs. The total number of rows in **M\_TetraPath** is 20 times the number of tetrahedra in the triangulation.

*format*=4: Saves a wave containing internal diagnostic information generated during the triangulation process.

## Details

Triangulate3d implements Watson's algorithm for tetrahedralization of a set of points in three dimensions. It starts by creating a very large tetrahedron which inscribes all the data points followed by a sequential insertion of one datum at a time. With each new datum the algorithm finds the tetrahedron in which the datum falls. It then proceeds to subdivide the tetrahedron so that the datum becomes a vertex of new tetrahedra.

Watson's algorithm suffers from two known problems. First, it may have numerical instabilities if resulting tetrahedra are too thin. The second problem involves memory allocations, which may be insufficient for some pathological spatial distributions of data points. Triangulate3d reports both problems in the history window.

## Examples

```
Make/O/N=(10,3) ddd=gnoise(5) // create random 10 points in space
Triangulate3d/out=2 ddd
// now display the triangulation in Gizmo:
Window Gizmo0() : GizmoPlot
  PauseUpdate; Silent 1
  if(exists("NewGizmo")!=4)
    DoAlert 0, "Gizmo XOP must be installed"
    return
  endif
  NewGizmo/N=Gizmo0 /W=(309,44,642,373)
  ModifyGizmo startRecMacro
  ModifyGizmo scalingMode=2
  AppendToGizmo Scatter=root:ddd,name=scatter0
  ModifyGizmo ModifyObject=scatter0 property={ scatterColorType,0}
  ModifyGizmo ModifyObject=scatter0 property={ Shape,2}
  ModifyGizmo ModifyObject=scatter0 property={ size,0.2}
  ModifyGizmo ModifyObject=scatter0 property={ color,0,0,0,1}
  AppendToGizmo Path=root:M_TetraPath,name=path0
  ModifyGizmo ModifyObject=path0 property={ pathColor,0,0,1,1}
  ModifyGizmo setDisplayList=0, object=scatter0
  ModifyGizmo setDisplayList=1, object=path0
  ModifyGizmo autoscaling=1
  ModifyGizmo compile
  ModifyGizmo endRecMacro
End
```

## try-catch-endtry

### **try**

*<possible abort code>*

### **catch**

*<code to handle abort>*

### **endtry**

A try-catch-endtry flow control statement provides a means for catching and responding to abort conditions in user functions.

When code executes in the try-catch area, any programmatic aborts will immediately jump to code within the catch-endtry area rather than jumping to the end of the user function. Normal flow (no aborts) will skip all code within the catch-endtry area.

## UniqueName

---

### Details

During execution of code in the catch-endtry area, user aborts are suppressed. This means that when the user attempts to abort procedure execution by holding down the appropriate abort key combination, it will not abort the catch code itself.

Whenever an abort occurs, information about the cause of the abort is returned via the following variable:

```
V_AbortCode = -4:   Abort triggered by AbortOnRTE.
              -3:   Abort caused by Abort operation.
              -2:   Stack overflow abort.
              -1:   User abort.
              ≥1:   Abort triggered by AbortOnValue.
```

### See Also

**Flow Control for Aborts** on page IV-37 and **try-catch-endtry Flow Control** on page IV-37 for further details.

The **AbortOnRTE** and **AbortOnValue** keywords, and the **Abort** operation.

## UniqueName

**UniqueName**(*baseName*, *objectType*, *startSuffix* [, *windowNameStr*])

The **UniqueName** function returns the concatenation of *baseName* and a number such that the result is not in conflict with any other object name.

*windowNameStr* is optional. If missing, it is taken to be the top graph, panel, layout, or notebook according to the value of *objectType*.

### Details

*baseName* should be an unquoted name, such as you might receive from the user via a dialog or control panel.

*objectType* is one of the following:

- |   |   |    |   |
|---|---|----|---|
| 1 | Wave.                                   | 9  | Control panel window.                                       |
| 2 | Reserved.                               | 10 | Notebook window.  |
| 3 | Numeric variable.                       | 11 | Data folder.  |
| 4 | String variable.                        | 12 | Symbolic path.  |
| 5 | XOP target window (e.g., surface plot). | 13 | Picture.  |
| 6 | Graph window.                           | 14 | Annotation in the named or topmost graph or layout.         |
| 7 | Table window.                           | 15 | Control in the named or topmost graph or panel.             |
| 8 | Layout window.                          | 16 | Notebook action character in the named or topmost notebook. |

*startSuffix* is the number used as a starting point when generating the numeric suffix that makes the name unique. Normally you should pass zero for *startSuffix*. If you know that names of the form *base0* through *baseN* are in use, you can make **UniqueName** run a bit faster by passing *N+1* as the *startSuffix*.

The *windowNameStr* argument is used only with *objectTypes* 14, 15, and 16. The returned name is unique only to the window (other windows might have objects with the same name). If a named window is given but does not exist, **UniqueName** returns *baseName startSuffix*. *windowNameStr* is ignored for other *objectTypes*.

### Examples

```
String uniqueWaveName = UniqueName(baseWaveName, 1, 0)
String uniqueControlName = UniqueName("ctrl", 15, 0, "Panel0")
```

### See Also

**CheckName** and **CleanupName**.

## Unwrap

**Unwrap** *modulus*, *waveName* [, *waveName*]...

The Unwrap operation scans through each named wave trying to undo the effect of a modulus operation.

### Parameters

*modulus* is the value applied to the named waves through the **mod** function as if the command:

```
waveName = mod(waveName,modulus)
```

had been executed. It is this calculation which Unwrap attempts to undo.

### Details

The unwrap operation works with 1D waves only. See **ImageUnwrapPhase** for phase unwrapping in two dimensions.

### Examples

If you perform an FFT on a wave, the result is a complex wave in rectangular coordinates. You can create a real wave that contains the phase of the result of the FFT with the command:

```
wave2 = imag(r2polar(wave1))
```

However, the rectangular to polar conversion leaves the phase information modulo  $2\pi$ . You can restore the phase information with the command:

```
Unwrap 2*pi, wave2
```

Because the first point of a wave that has been FFTed has no phase information, in this example you would *precede* the Unwrap command with the command:

```
wave2[0] = wave2[1]
```

### See Also

The **ImageUnwrapPhase** operation and **mod** function.

## UpperStr

**UpperStr** (*str*)

The UpperStr function returns a string expression in which all lower-case characters in *str* are converted to upper-case.

### See Also

The **LowerStr** function.

## ValDisplay

**ValDisplay** [/Z] *ctrlName* [*key* [= *value*]][, *key* [= *value*]]...

The ValDisplay operation creates or modifies the named control that displays a numeric value in the target window. The appearance of the control varies; see the **Examples** section.

For information about the state or status of the control, use the **ControlInfo** operation.

### Parameters

*ctrlName* is the name of the ValDisplay control to be created or changed.

*key* is one of the following parameters:

appearance={*kind* [, *platform*]}

Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

*kind* can be one of **default**, **native**, or **os9**.

*platform* can be one of **Mac**, **Win**, or **All**.

See **Button** and **DefaultGuiControls** for more appearance details.

barmisc={*lts*, *valwidth*}

Sets the “limits text size” and the size of the type showing the bar limits. If *lts* is zero, the bar limits are not displayed. Otherwise, *lts* must be between 5 and 100.

*valwidth* is the “value readout width”. It claims the amount of horizontal space for the numeric part of the display.

If *valwidth* equals or exceeds the control width available to it, the numeric readout uses all the room, and prevents display of any bar.

	<p>If <i>valwidth</i> is zero, there is no numeric readout, and only the bar is displayed. <i>valwidth</i> can range from zero to 4000, and it defaults to 1000 (which usually leaves no room for the display bar).</p>
<code>bodyWidth=<i>width</i></code>	<p>Specifies an explicit size for the body (nontitle) portion of a ValDisplay control. By default (<code>bodyWidth=0</code>), the body portion is the amount left over from the specified control width after providing space for the current text of the title portion. If the font, font size, or text of the title changes, then the body portion may grow or shrink. If you supply a <code>bodyWidth&gt;0</code>, then the body is fixed at the size you specify regardless of the body text. This makes it easier to keep a set of controls right aligned when experiments are transferred between Macintosh and Windows, or when the default font is changed.</p>
<code>disable=<i>d</i></code>	<p>Sets user editability of the control.</p> <ul style="list-style-type: none"><li><code>d=0</code>: Normal.</li><li><code>d=1</code>: Hide.</li><li><code>d=2</code>: Disable user input. Does not change control appearance because it is read-only.</li></ul>
<code>font="<i>fontName</i>"</code>	<p>Sets the font used to display the value of the variable, e.g., <code>font="Helvetica"</code>.</p>
<code>format=<i>formatStr</i></code>	<p>Sets the numeric format of the displayed value. The default format is "%g". For a description of <i>formatStr</i>, see the <b>printf</b> operation.</p>
<code>frame=<i>f</i></code>	<p>Sets frame style.</p> <ul style="list-style-type: none"><li><code>f=0</code>: Value is unframed.</li><li><code>f=1</code>: Default; value is framed (same as <code>f=3</code>).</li><li><code>f=2</code>: Simple box.</li><li><code>f=3</code>: 3D sunken frame.</li><li><code>f=4</code>: 3D raised frame.</li><li><code>f=5</code>: Text well.</li></ul>
<code>fsize=<i>s</i></code>	<p>Sets the size of the type used to display the value in the numeric readout. The default is 12 points.</p>
<code>fstyle=<i>fs</i></code>	<p><i>fs</i> is a binary coded number with each bit controlling one aspect of the font style as follows:</p> <ul style="list-style-type: none"><li>bit 0: Bold.</li><li>bit 1: Italic.</li><li>bit 2: Underline.</li><li>bit 3: Outline (<i>Macintosh only</i>).</li><li>bit 4: Shadow (<i>Macintosh only</i>).</li></ul> <p>See <b>Setting Bit Parameters</b> on page IV-11 for details about bit settings.</p>
<code>help={<i>helpStr</i>}</code>	<p>Sets the help for the control. The help text is limited to a total of 255 characters. On Macintosh, help appears when you turn Igor Tips on. On Windows, help for the first 127 characters or up to the first line break appears in the status line. If you press F1 while the cursor is over the control, you will see the entire help text. You can insert a line break by putting "\r" in a quoted string.</p>
<code>highColor=(<i>r,g,b</i>)</code>	<p>Specifies the bar color when the value is greater than <i>base</i> in the limits keyword. <i>r</i>, <i>g</i>, and <i>b</i> are integers from 0 to 65535.</p>
<code>labelBack=(<i>r,g,b</i>)</code> or 0	<p>Specifies the background fill color for labels. <i>r</i>, <i>g</i>, and <i>b</i> are integers from 0 to 65535. The default is 0, which uses the window's background color.</p>
<code>limits={<i>low,high,base</i>}</code>	<p>Controls how the value is translated into a graphical representation when the display includes a bar (described fully in <b>Details</b>). Defaults are {0,0,0}, which aren't too useful.</p>
<code>lowColor=(<i>r,g,b</i>)</code>	<p>Specifies the bar color when the value is less than <i>base</i> in the limits keyword. <i>r</i>, <i>g</i>, and <i>b</i> are integers from 0 to 65535.</p>
<code>mode=<i>m</i></code>	<p>Specifies the type of LED display to use, if any.</p> <ul style="list-style-type: none"><li><code>m=0</code>: Bar mode (default).</li><li><code>m=1</code>: Oval LED.</li></ul>

	$m=2$ :	Rectangular LED.
	$m=3$ :	Bar mode with no fractional part.
<code>pos={left,top}</code>		Sets position of display in pixels, from 0 to 2000.
<code>rename=newName</code>		Gives the ValDisplay control a new name.
<code>size={width,height}</code>		Sets width and height of display in pixels. <i>width</i> can range from 10 to 200 pixels, <i>height</i> from 5 to 200 pixels. Default width is 50, default height is determined by the numeric readout font size.
<code>title=titleStr</code>		Sets title of display to the specified string expression. The title appears to the left of the display. If this title is too long, it won't leave enough room to display the bar or even the numeric readout!
<code>value=valExpr</code>		Displays the numeric expression <i>valExpr</i> . It is <i>not</i> a string.
<code>win=winName</code>		Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed. When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy.
<code>zeroColor=(r,g,b)</code>		Governs the LED color (in LED mode only). <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535. Used in conjunction with the <code>limits</code> keyword such that <code>zeroColor</code> determines one endpoint color when base is between <i>low</i> and <i>high</i> , or LED color when the value is less than <i>low</i> .

**Flags**

/Z No error reporting.

**Details**

The target window must be a graph or panel.

The appearance of the ValDisplay control depends primarily on the *width* and *valwidth* parameters and the width of the title. Space for the individual elements is allocated from left to right, with the title receiving first priority. If the control width hasn't all been used by the title, then the value display gets either *valwidth* pixels of room, or what is left. If the control width hasn't been used up, the bar is displayed in the remaining control width:

If you use the `bodyWidth` keyword, the value readout width and bar width occupy the body width. The total control width is then `bodyWidth+title width`, and the width from the `size` keyword is ignored.

The limits values *low*, *high*, and *base* and the value of *valExpr* control how the bar, if any, is drawn. The bar is drawn from a starting position corresponding to the *base* value to an ending position determined by the value of *valExpr*, *low* and *high*. *low* corresponds to the left side of the bar, and *high* corresponds to the right. The position that corresponds to the *base* value is linearly interpolated between *low* and *high*.

For example, with *low*= -10, *high*=10, and *base*= 0, a *valExpr* value of 5 will draw from the center of the bar area (0 is centered between -10 and 10) to the right, halfway from the center to the right of the bar area (5 is halfway from 0 to 10):

The *valExpr* must be executable at any time. The expression is stored and executed when the ValDisplay needs to be updated. However, execution will occur outside the routine that creates the ValDisplay, so you must not use local variables in the expression.

*valExpr* may be enclosed in quotes and preceded with a # character (see **When Dependencies are Updated** on page IV-174) to defer evaluation of the validity of the numeric expression, which may be needed if the expression references as-yet-nonexistent global variables or user-defined functions:

```
ValDisplay valdisp0 value=notAVar*2           // "unknown name or symbol" error
ValDisplay valdisp0 value=#"notAVar*2"       // still not valid, no error
Variable notAVar=3                           // now valid; ValDisplay works
```

In a ValDisplay, the # " " syntax permits use of a string expression. Normally, the # prefix signifies that the following text must be a literal quoted string. String expressions are evaluated at runtime to obtain the final expression for the ValDisplay. In other words, there is a level of indirection.

## Examples

Here is a sampling of the various types of ValDisplay controls available:

You can use a ValDisplay to replace the bar mode with a solid color fill designed to look like an LED. Use the mode keyword with mode=1 to create an oval LED or mode=2 to create a rectangular LED. You can specify different frames with the rectangular LED but only a simple frame is available for the oval mode. Use mode=0 to revert to bar mode.

The color and brightness of the LED depends on the value that the ValDisplay is monitoring combined with the limits={*low*, *high*, *base*} setting, the two color settings used in bar mode along with a third color (zeroColor) that is used only in LED mode. When the value is between *low* and *high*, the color is a linear combination of endpoint colors. If *base* is between *low* and *high*, the endpoint colors are the low color and the zero color, or the zero color and the high color. For values outside the limits, the appropriate limiting color is chosen.

If *base* is less than the *low*, the endpoint colors are the low color and the high color. In this case, if the value is less than *low* the LED takes on the zero color.

You should use the bodyWidth setting in conjunction with LED mode to keep the LED from dramatically changing size or disappearing when the title is changed or if your experiment is moved to a different platform (Macintosh vs PC).

Try the ValDisplay Demo example experiment to see these different modes in action. The experiment file is in your Igor Pro folder, in the "Examples:Feature Demos" subfolder.

**See Also**

See **ValDisplay** on page III-366 for more examples, and the **printf** operation about *formatStr*.

The **ControlInfo** operation for information about the control. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **GetUserData** operation for retrieving named user data.

**Variable**

**Variable** [*flags*] *varName* [=*numExpr*][, *varName* [=*numExpr*]]...

The Variable declaration creates real or complex variables and gives them the specified name.

**Flags**

- /C Declares a complex variable.
- /D Obsolete, included only for backward compatibility (see **Details**).
- /G Creates a variable with global scope and overwrites any existing variable.

**Details**

The variable is initialized when it is created if you supply the initial value. You can create more than one variable at a time by separating the names and optional initializers for multiple variables with a comma.

As of Igor Pro 2.02 for Power Macintosh, Igor Pro 3.0 for all Macintoshes, and for all Windows versions, all numeric variables are double precision. Previously variables could be single or double precision and the /D flag meant double precision. The /D flag is allowed for backward compatibility but is no longer needed and should not be used in new code.

If used in a macro or function the new variable is local to that macro or function unless the /G (global) flag is used. If used on the command line, the new variable is global.

*varName* can include a data folder path.

**Examples**

To initialize a complex variable, use the **cmplx** function. For example:

```
Variable/C cv1 = cmplx(1,2)
```

sets the real part of cv1 to 1 and the imaginary part to 2.

**VariableList**

**VariableList**(*matchStr*, *separatorStr*, *variableTypeCode*)

The VariableList function returns a string containing a list of global variables selected based on the *matchStr* and *variableTypeCode* parameters. The variables listed are all in the current data folder.

**Details**

For a variable name to appear in the output string, it must match *matchStr* and also must fit the requirements of *variableTypeCode*. The first character of *separatorStr* is appended to each variable name as the output string is generated.

The name of each variable is compared to *matchStr*, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

- "\*" Matches all variable names.
- "xyz" Matches variable name xyz only.
- "\*xyz" Matches variable names which end with xyz.
- "xyz\*" Matches variable names which begin with xyz.
- "\*xyz\*" Matches variable names which contain xyz.
- "abc\*xyz" Matches variable names which begin with abc and end with xyz.

*matchStr* may begin with the ! character to return windows that do not match the rest of *matchStr*. For example:

- "!\*xyz" Matches variable names which *do not* end with xyz.

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of *matchStr*.

*variableTypeCode* is used to further qualify the variable. The variable name goes into the output string only if it passes the match test and its type is compatible with *variableTypeCode*. *variableTypeCode* is any one of:

- 2: 32-bit (single precision) floating point numbers.
- 4: 64-bit (double precision) floating point numbers.

or a bitwise combination of the above for more than one type of variable. However, as of Igor Pro 3.0, only system numeric variables (K0, K1, ... K19, and veclen) are single precision, so you can usually use just 4 (double precision).

VariableList by default returns only real variables; to get a list of only complex variables, add one to *varTypeCode*:

- 1: For complex numbers only.

### Examples

VariableList("\*, ";" , 4+2) Returns a list of all real single- and double-precision floating point variables.

VariableList("!V\_\*", ";" , 4+1) Returns a list of all complex double-precision floating point variables except those whose names begin with "V\_".

VariableList("\*, ";" , 6) + VariableList("\*, ";" , 7) Returns a list of all variables in the current data folder.

### See Also

See the **StringList** and **WaveList** functions.

See **Setting Bit Parameters** on page IV-11 for details about bit settings.

## VCSR

**vcsr(cursorName [, graphNameStr])**

The vcsr function returns the Y (vertical) value of the point which the specified cursor (A through J) is attached to in the top (or named) graph.

### Parameters

*cursorName* identifies the cursor, which can be cursor A through J.

*graphNameStr* specifies the graph window or subwindow.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

### Details

The result is computed from the coordinate system of the graph's Y axis. The Y axis used is the one used to display the wave on which the cursor is placed.

### See Also

## version

**#pragma version = versNum**

In the File Information dialog, **#pragma version=versNum** provides file version information that is displayed next to the file name in the dialog. This line must not be indented and must appear in the first five lines of the file. See **Procedure File Version Information** on page IV-120.

### See Also

The **The version Pragma** on page IV-39, **Procedure File Version Information** on page IV-120, the **IgorInfo** function, and **#pragma**.

## WAVE

**WAVE [/C][/T][/Z] localName [=pathToWave][, localName1 [=pathToWave1]]...**

WAVE is a reference that identifies the nature of a user-defined function parameter or creates a local reference to a wave accessed in the body of a user-defined function.

The optional parameter *pathToWave* is used only in the body of a function, not in a parameter declaration.

The WAVE reference is required when you use a wave in an assignment statement in a function. At compile time, the WAVE statement specifies that the local name references a wave. At runtime, it makes the connection between the local name and the actual wave. For this connection to be made, the wave must exist when the WAVE statement is executed.

When *localName* is the same as the global wave name and you want to reference a wave in the current data folder, you can omit the *pathToWave*. Prior to Igor Pro 4.0, *pathToWave* was always required.

*pathToWave* can be a full literal path (e.g., root:FolderA:wave0), a partial literal path (e.g., :FolderA:wave0) or \$ followed by string variable containing a computed path (see **Converting a String into a Reference Using \$** on page IV-48).

If the wave may not exist at runtime, use the /Z flag and call **WaveExists** before accessing the wave. The /Z flag prevents Igor from flagging a missing wave as an error and dropping into the debugger. For example:

```
WAVE/Z wv=<pathToPossiblyMissingWave>
if( WaveExists(wv) )
    <do something with wv>
endif
```

Note that to create a wave, you use the **Make** operation.

### Flags

/C        Complex wave.  
 /T        Text wave.  
 /Z        Ignores wave reference checking failures.

### See Also

**WaveExists** function and **Runtime Lookup of Globals** on page IV-50.

**Converting a String into a Reference Using \$** on page IV-48.

## WAVEClear

**WAVEClear** *localName* [, *localName1* ...]

The WAVEClear operation clears out a WAVE reference variable. WAVEClear is equivalent to `WAVE/Z localName= "$"`.

### Details

Use WAVEClear to avoid unexpected results from certain operations such as **Duplicate** or **Concatenate**, which will reuse the contents of a WAVE reference variable and may not generate the wave in the desired data folder or with the desired name.

WAVEClear ensures that memory is deallocated after waves are killed as in this example:

```
Function foo()
    Make wave1
    FunctionThatKillsWave1()
    WAVEClear wave1
    AnotherFunction()
End
```

Although memory used for wave1 will be deallocated when `foo` returns, that memory will not be automatically released while the function executes because the WAVE variable still contains a reference to the wave. In this example, WAVEClear deallocates that memory before `AnotherFunction` executes.

You can also use WAVEClear before passing a data folder to preemptive threads using **ThreadGroupPutDF**.

### See Also

**Accessing Waves in Functions** on page IV-57, **Wave Reference Counting** on page IV-151, and **ThreadSafe Functions and Multitasking** on page IV-214.

### WaveCRC

**WaveCRC**(*inCRC*, *waveName* [, *checkHeader*])

The WaveCRC function returns 32 bit cyclic redundancy check value of the bytes in the named wave starting with *inCRC*, which should be zero for the first (or only) set of bytes.

*waveName* may be a numeric or text wave.

The optional *checkHeader* parameter determines how much of the wave is checked:

<i>checkHeader</i>	What It Does
0	Check only the wave data (default).
1	Check only the internal binary header.
2	Check both.

#### Details

Polynomial used is:

$$x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^8+x^7+x^5+x^4+x^2+x+1$$

See `crc32.c` in the public domain source code for `zlib` for more information.

#### See Also

The **stringCRC** function.

### WaveDims

**WaveDims**(*wave*)

The WaveDims function returns the number of dimensions used by *wave*.

Returns zero if wave reference is null. See **WaveExists** for a discussion of null wave references.

Also returns zero if wave has zero rows. A matrix will return 2.

### WaveExists

**WaveExists**(*wave*)

The WaveExists function returns one if wave reference is valid or zero if the wave reference is null. For example if, in a user function, you have:

```
Wave w= $"no such wave"
```

```
then WaveExists(w) will return zero.
```

WaveExists should be used in functions only. In macros, use the `exists` function instead.

#### See Also

`exists`, `NVAR_Exists`, `SVAR_Exists`, and **Runtime Lookup of Globals** on page IV-50.

### WaveInfo

**WaveInfo**(*waveName*, 0)

The WaveInfo function returns a string containing a semicolon-separated list of information about the named wave.

#### Details

The string contains six kinds of information. Each group is prefaced by a keyword and colon, and terminated with a semicolon. The keywords are:

Keyword	Information Following Keyword
DUNITS	The data units (y scaling units, zero to three characters).
FULLSCALE	Three numbers indicating whether the wave has any data full scale information, and the min and max data full scale values. The format of the FULLSCALE description is: <code>FULLSCALE:validFS,minFS,maxFS;</code>

Keyword	Information Following Keyword
	<i>validFS</i> is 1 if <i>minFS</i> and <i>maxFS</i> have been set via a <code>SetScale</code> command; otherwise it is 0.
LOCK	Reads back the value set by <code>SetWaveLock</code> .
MODIFIED	1 if the wave has been modified since the experiment was last saved, else 0.
MODTIME	The date and time that the wave was last modified in seconds since January 1, 1904.
NUMTYPE	A number denoting the numerical type of the wave: 1: Complex, added to one of the following: 2: 32-bit (single precision) floating point 4: 64-bit (double precision) floating point 8: 8-bit signed integer 16: 16-bit signed integer 32: 32-bit signed integer 64: Unsigned, added to 8, 16, or 32 if wave is unsigned  For example, the number denoting a complex double precision wave is 5 (i.e., 1+4). See <b>Setting Bit Parameters</b> on page IV-11 for details about bit settings.
PATH	The name of the symbolic path in which the wave file is stored (e.g., <code>PATH:home;</code> ) or nothing if there is no path for the wave ( <code>PATH:;</code> ).
XUNITS	The X units (X scaling units, zero to three characters).

Always pass 0 as the second input parameter. In future versions of Igor, this parameter may request other kinds of information to be returned.

A null wave reference returns a zero-length string. This might be encountered, for instance, when using `WaveRefIndexed` in a loop to act on all waves accessed by **WaveRefIndexed**, and the loop has incremented beyond the highest valid index.

### Examples

```
Make/O wavel;SetScale x,0,1,"dyn",wavel;SetScale y,3,20,"v",wavel
String info = WaveInfo(wavel,0)
Print NumberByKey("NUMTYPE", info)           // Prints 2
Print StringByKey("DUNITS", info)            // Prints "v"
```

### See Also

The functions and operations listed under “About Waves” categories in the Command Help tab of the Igor Help Browser; among them are **CreationDate**, **modDate**, **WaveType**, **note**, and **numpnts**.

**NumberByKey** and **StringByKey** functions for parsing the returned keyword list.

`WaveInfo` lacks information about multidimensional waves. Individual functions are provided to return dimension-related information: **DimDelta**, **DimOffset**, **DimSize**, **WaveUnits**, and **GetDimLabel**.

## WaveList

### **WaveList**(*matchStr*, *separatorStr*, *optionsStr*)

The `WaveList` function returns a string containing a list of waves selected from the current data folder based on *matchStr* and *optionsStr* parameters. See **Details** for information on listing waves in graphs, and for references to newer, data folder-aware functions.

### Details

For a wave name to appear in the output string, it must match *matchStr* and also must fit the requirements of *optionsStr* and it must be in the current data folder. The first character of *separatorStr* is appended to each wave name as the output string is generated.

The name of each wave is compared to *matchStr*, which is some combination of normal characters and the asterisk wildcard character that matches anything.

For example:

"\*" Matches all wave names in current data folder.

## WaveList

---

- "xyz" Matches wave name xyz only, if xyz is in the current data folder.
- "\*xyz" Matches wave names which end with xyz and are in the current data folder.
- "xyz\*" Matches wave names which begin with xyz and are in the current data folder.
- "\*xyz\*" Matches wave names which contain xyz and are in the current data folder.
- "abc\*xyz" Matches wave names which begin with abc and end with xyz and are in the current data folder.

*matchStr* may begin with the ! character to return windows that do not match the rest of *matchStr*. For example:

- "!\*xyz" Matches wave names which do not end with xyz.

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of *matchStr*.

*optionsStr* is used to further qualify the wave.

Use "" to accept all waves in the current data folder that are permitted by *matchStr*.

Set *optionsStr* to one or more of the following comma-separated keyword-value pairs:

<i>optionsStr</i>	Selection Criteria
"BYTE:0" or "BYTE:1"	Waves that are not 8-bit integer (if 0) or only waves that are 8-bit integer (if 1).
"CMPLX:0" or "CMPLX:1"	Waves that are not complex (if 0) or only waves that are complex (if 1).
"DIMS: <i>numberOfDims</i> "	All waves in current data folder that have <i>numberOfDims</i> dimensions. This is the number of dimensions reported by <b>WaveDims</b> . Use "DIMS:0" for all waves having no points ( <code>numpts(w)==0</code> ). Use "DIMS:1" for graph traces (or one of the X, Y, and Z waves of a contour plot). Use "DIMS:2" for false color and indexed color images (see <b>Indexed Color Details</b> on page II-333). Use "DIMS:3" for direct color images (see <b>Direct Color Details</b> on page II-336).
"DP:0" or "DP:1"	Waves that are not double precision floating point (if 0) or only waves that are double precision floating point (if 1).
"INTEGER:0" or "INTEGER:1"	Waves that are not 32-bit integer (if 0) or only waves that are 32-bit integer (if 1).
"MAXCHUNKS: <i>max</i> "	Waves having no more than <i>max</i> chunks.
"MAXCOLS: <i>max</i> "	Waves having no more than <i>max</i> columns.
"MAXLAYERS: <i>max</i> "	Waves having no more than <i>max</i> layers.
"MAXROWS: <i>max</i> "	Waves having no more than <i>max</i> rows.
"MINCHUNKS: <i>min</i> "	Waves having at least <i>min</i> chunks.
"MINCOLS: <i>min</i> "	Waves having at least <i>min</i> columns.
"MINLAYERS: <i>min</i> "	Waves having at least <i>min</i> layers.
"MINROWS: <i>min</i> "	Waves having at least <i>min</i> rows.
"SP:0" or "SP:1"	Waves that are not single precision floating point (if 0) or only waves that are single precision floating point (if 1).
"TEXT:0" or "TEXT:1"	Waves that are not text (if 0) or only waves that are text (if 1).
"UNSIGNED:0" or "UNSIGNED:1"	Waves that are not unsigned integer (if 0) or only waves that are unsigned integer (if 1).
"WIN:"	All waves in the current data folder that are displayed in the top graph or table.

<i>optionsStr</i>	Selection Criteria
"WIN: <i>windowName</i> "	All waves in the current data folder that are displayed in the named table or graph window or subwindow.
"WORD: 0" or "WORD: 1"	Waves that are not 16-bit integer (if 0) or only waves that are 16-bit integer (if 1).

You can specify more than one option by separating the options with a comma. See the **Examples**.

**Note:** Even when *optionsStr* is used to list waves used in a graph or table, the waves must be in the current data folder.

**Note:** In addition to waves displayed as normal graph traces, WaveList will list matrix waves used with **AppendImage** or **NewImage** and the X, Y, and Z waves used with **AppendXYZContour**.

**Note:** Individual contour traces are not listed because they have no corresponding waves. See **All About Contour Traces** on page II-306.

There are several functions that are more useful for listing waves in graphs and tables.

WaveList with WIN: *windowName* gives only the names of the waves in the graph or table and does not include the data folder for each wave. If you need to know what data folder the waves are in, use **WaveRefIndexed** to get the wave itself and then if needed use **GetWavesDataFolder** to get the path.

When identifying a subwindow with WIN: *windowName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

To list the actual waves used in a graph, or to distinguish two or more instances of the same named wave in a graph, use **TraceNameList**. This function can be used in conjunction with **TraceNameToWaveRef**, and **XWaveRefFromTrace**.

Use **ContourNameList** to list contour plots in a given window and **ContourNameToWaveRef** to access the waves used to generate the contour plot.

To list the contour traces (that is, the contour lines themselves) use **TraceNameList** with the appropriate option.

Use **ImageNameList** to list images in a given window and **ImageNameToWaveRef** to access the waves used to generate the images.

### Examples

WaveList("*", ";", "")	Returns a list of all waves in the current data folder.
WaveList("*", ";", "WIN:")	Returns a list of all waves in the current data folder and displayed in the top table or graph.
WaveList("*_bkg", ";", "WIN:Graph0")	Returns a list of waves in the current data folder whose names end in "_bkg" and which are displayed in Graph0 as 1D traces.
WaveList("!*X", ";", "WIN:Graph0, DIMS:1")	Returns a list of waves in the current data folder whose names do not end in "X" and which are displayed in Graph0 as 1D traces or as one of the X, Y, and Z waves of an AppendXYZContour plot.

Contrary to what you might expect, you can *not* use the output of WaveList directly with operations that have a list of waves as their parameters. See **Processing Lists of Waves** on page IV-144 for ways of dealing with this.

### See Also

Chapter II-6, **Multidimensional Waves**.

Execute, **ContourNameList**, **ImageNameList**, **TraceNameList**, and **WaveRefIndexed**.

## waveMax

**waveMax(waveName [, x1, x2])**

The waveMax function returns the maximum value in the wave for points between  $x=x1$  to  $x=x2$ , inclusive.

### Details

If  $x1$  and  $x2$  are not specified, they default to  $-\text{inf}$  and  $+\text{inf}$ , respectively.

The X scaling of the wave is used only to locate the points nearest to  $x=x1$  and  $x=x2$ . To use point indexing, replace  $x1$  with  $\text{pnt}2x(\text{waveName}, \text{pointNumber}1)$ , and a similar expression for  $x2$ .

## WaveMeanStdv

---

If the points nearest to  $x1$  or  $x2$  are not within the point range of 0 to  $\text{numpts}(\text{waveName})-1$ , `waveMax` limits them to the nearest of point 0 or point  $\text{numpts}(\text{waveName})-1$ .

For a floating-point wave, `waveMax` runs about three times faster than getting the same information using `waveStats`. For an integer wave, `waveMax` runs about ten times faster than `waveStats`. The advantage may not hold for short waves.

### See Also

The `waveMin` function and `WaveStats` operation.

## WaveMeanStdv

### **WaveMeanStdv** *srcWave binSizeWave*

The `WaveMeanStdv` operation calculates the standard deviation of the means for the specified bin distribution saving the result in the wave `W_MeanStdv`.

For each entry in *binSizeWave*, *srcWave* is divided into the specified number of bins. Values in each bin are averaged and then the mean and standard deviation of the averages (among all bins) are calculated. The value of the standard deviation of the bin averages divided by the mean is then stored in `W_MeanStdv` corresponding to the bin size entry in *binSizeWave*.

All entries in *binSizeWave* must be positive integers.

### Details

When the number of points in *srcWave* does not divide evenly into the bin size entry from *binSizeWave*, the last bin will have a smaller number of data points. In order not to skew the results the values corresponding to the last bin will be dropped. If your data set is small compared to the bin size you might want to pad *srcWave* with additional values (e.g., duplicate values from the beginning of the wave).

This operation does not support NaNs. If you get a NaN as an entry in the output wave then there is either a NaN in *srcWave* or something is wrong with the calculation for that entry.

## waveMin

### **waveMin**(*waveName* [, *x1*, *x2*])

The `waveMin` function returns the minimum value in the wave for points between  $x=x1$  to  $x=x2$ , inclusive.

### Details

If  $x1$  and  $x2$  are not specified, they default to  $-\text{inf}$  and  $+\text{inf}$ , respectively.

The X scaling of the wave is used only to locate the points nearest to  $x=x1$  and  $x=x2$ . To use point indexing, replace  $x1$  with  $\text{pnt}2x(\text{waveName}, \text{pointNumber}1)$ , and a similar expression for  $x2$ .

If the points nearest to  $x1$  or  $x2$  are not within the point range of 0 to  $\text{numpts}(\text{waveName})-1$ , `waveMin` limits them to the nearest of point 0 or point  $\text{numpts}(\text{waveName})-1$ .

For a floating-point wave, `waveMin` runs about three times faster than getting the same information using `waveStats`. For an integer wave, `waveMin` runs about ten times faster than `waveStats`. The advantage may not hold for short waves.

### See Also

The `waveMax` function and `WaveStats` operation.

## WaveName

### **WaveName**(*winNameStr*, *index*, *type*)

The `WaveName` function returns a string containing the name of the *index*th wave of the specified *type* in the named window or subwindow.

### Parameters

*winNameStr* can be "" to refer to the top graph or table.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**Details**

WaveName works on waves displayed in a graph, in a table or on the list of waves in the current data folder. If the window is a table, WaveName returns the column name (e.g., "wave0.d"), rather than the name of the wave itself (e.g., "wave0").

For most uses, we recommend that you use **WaveRefIndexed** instead of WaveName. WaveName returns a string containing the wave name only, with no data folder path qualifying it. Thus, you may get erroneous results if the wave referred to in the graph has the same name as a different wave in the current data folder. Likewise, if the named wave resides in a data folder that is not the current data folder, you will not be able to refer to the named wave.

*winNameStr* is a string expression containing the name of a graph or table or the null string (""). If the string is null and *type* is 4 then WaveName works on the list of all waves in the current data folder. If the string is null and the type parameter is not 4 then WaveName works on the top graph or table.

*index* starts from zero.

*type* is a number from 1 to 4. When *type* is 4 and *winNameStr* is "", WaveName works on the list of all waves in the current data folder.

For graph windows, *type* is 1 for y waves, 2 for x waves, 3 for either y or x waves.

For table windows, *type* is 1 for data columns, 2 for index or dimension label columns, 3 for either data or index or dimension label columns.

WaveName returns the null string ("") if there is no wave matching the parameters.

**Examples**

```
WaveName("",0,4)      // Returns name first wave current data folder.
WaveName("",0,1)      // Returns name of first Y wave in the top graph.
WaveName("Graph0",1,2) // Returns name of second X wave in Graph0.
WaveName("Table0",1,3) // Returns name of second column in Table0.
```

**WaveRefIndexed****WaveRefIndexed(winNameStr, index, type)**

The WaveRefIndexed function returns a wave reference to the *index*th wave of the specified *type* in the named window or subwindow.

**Parameters**

*winNameStr* can be "" to refer to the top graph or table window or the current data folder.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**Details**

WaveRefIndexed is analogous to WaveName but works better with data folders. We recommend that you use it instead of WaveName.

*winNameStr* is a string expression containing the name of a graph or table or the null string (""). If the string is null and *type* is 4 then WaveRefIndexed works on Igor's list of all waves in the current data folder. If the string is null and the type parameter is not 4 then WaveRefIndexed works on the top graph or table.

*index* starts from zero.

*type* is a number from 1 to 4. When *type* is 4 and *winNameStr* is "", WaveRefIndexed works on the list of all waves in the current data folder.

For graph windows, *type* is 1 for y waves, 2 for x waves, 3 for either y or x waves.

For table windows, *type* is 1 for data columns, 2 for index or dimension label columns, 3 for either data or index or dimension label columns.

WaveRefIndexed returns a null reference (see **WaveExists**) if there is no wave matching the parameters.

**Examples**

```
WaveRefIndexed("",0,4)      // Returns first wave in current data folder.
WaveRefIndexed("",0,1)      // Returns first Y wave in the top graph.
WaveRefIndexed("Graph0",1,2) // Returns second X wave in Graph0.
WaveRefIndexed("Table0",1,3) // wave in second column in Table0.
```

## WaveStats

The `NameOfWave` and `GetWavesDataFolder` functions.

For a discussion of wave references, see **Wave Reference Functions** on page IV-143.

## WaveStats

### WaveStats [ *flags* ] *waveName*

The WaveStats operation computes several statistics on the named wave.

#### Flags

<code>/ALPH=<i>val</i></code>	Sets the significance level for the confidence interval of the mean (default <i>val</i> =0.05).
<code>/C=<i>method</i></code>	Calculates statistics for complex waves only. Does not affect real waves. You can use <i>method</i> in various combinations to process the real, imaginary, magnitude, and phase of the wave. The result is stored in the wave M_WaveStats (see <b>Details</b> for format). <i>method</i> =0: Default; ignores the imaginary part of <i>waveName</i> . Use <code>/W</code> to also store statistics in M_WaveStats. <i>method</i> =1: Calculates statistics for real part of <i>waveName</i> and stores it in M_WaveStats. <i>method</i> =2: Calculates statistics for imaginary part of <i>waveName</i> and stores the result in M_WaveStats. <i>method</i> =4: Calculates statistics for magnitude of <i>waveName</i> , i.e., $\sqrt{\text{real}^2 + \text{imag}^2}$ , and stores the result in M_WaveStats. <i>method</i> =8: Calculate statistics for phase of <i>waveName</i> using $\text{atan2}(\text{imag}, \text{real})$ . If you use a single <i>method</i> the results are stored both in M_WaveStats and in the standard variables (e.g., V_avg, etc.). If you specify <i>method</i> as a combination of more than one binary field then the variables reflect the results for the lowest chosen field and all results are stored in the wave M_WaveStats. For example, if you use <code>/C=12</code> , the variables will be set for the statistics of the magnitude and M_WaveStats will contain columns corresponding to the magnitude and to the phase. In this mode V_numInfs will always be zero. <b>Note:</b> if you invoke this operation and M_WaveStats already exists in the current data folder, it will be either overwritten or initialized to NaN.
<code>/M=<i>moment</i></code>	Calculates statistical moments. <i>moment</i> =1: Calculates only lower moments: V_avg, V_npnts, V_numInfs, and V_numNaNs. Use it if you do not need the higher moments. <i>moment</i> =2: Default; calculates both lower moments and higher order quantities: V_sdev, V_rms, V_adev, V_skew, and v_kurt.
<code>/Q</code>	Prevents results from being printed in history.
<code>/R=(<i>startX</i>,<i>endX</i>)</code>	Specifies an X range of the wave to evaluate.
<code>/R=[<i>startP</i>,<i>endP</i>]</code>	Specifies a point range of the wave to evaluate. If you specify the range as <code>/R=[<i>startP</i>]</code> then the end of the range is taken as the end of the wave. If <code>/R</code> is omitted, the entire wave is evaluated.
<code>/W</code>	Stores results in the wave M_WaveStats in addition to the various V_ variables when <code>/C=0</code> .
<code>/Z</code>	No error reporting.
<code>/ZSCR</code>	Computes z scores, $z_i = (Y_i - \bar{Y})/\sigma$ , saved in W_ZScore.

#### Details

WaveStats uses a two-pass algorithm to produce more accurate results than obtained by computing the binomial expansions of the third and fourth order moments.

WaveStats returns the statistics in the automatically created variables:

V_npnts	Number of points. Does not include points whose value is NaN or INF.
V_numNaNs	Number of NaNs.

V_numINFs	Number of INFs.
V_avg	Average of Y values.
V_sdev	Standard deviation of Y values, $\sigma = \sqrt{\frac{1}{V_{npnts} - 1} \sum (Y_i - V_{avg})^2}$ . ("Variance" is $V_{sdev}^2$ .)
V_rms	RMS (Root Mean Square) of Y values = $\sqrt{\frac{1}{V_{npnts}} \sum Y_i^2}$ .
V_adev	Average deviation = $\frac{1}{V_{npnts}} \sum_{i=0}^{V_{npnts}-1}  x_i - \bar{x} $ .
V_skew	Skewness = $\frac{1}{V_{npnts}} \sum_{i=0}^{V_{npnts}-1} \left[ \frac{x_i - \bar{x}}{\sigma} \right]^3$ .
V_kurt	Kurtosis = $\frac{1}{V_{npnts}} \sum_{i=0}^{V_{npnts}-1} \left[ \frac{x_i - \bar{x}}{\sigma} \right]^4 - 3$ .
V_minloc	X location of minimum Y value.
V_min	Minimum Y value.
V_maxloc	X location of maximum Y value.
V_max	Maximum Y value.
V_minRowLoc	Row containing minimum Z value (2D or higher waves).
V_minColLoc	Column containing minimum Z value (2D or higher waves).
V_maxColLoc	Column containing maximum Z value (2D or higher waves).
V_maxRowLoc	Row containing maximum Z value (2D or higher waves).
V_minLayerLoc	Layer containing minimum Z value (3D or higher waves).
V_maxLayerLoc	Layer containing maximum Z value (3D or higher waves).
V_minChunkLoc	Chunk containing minimum Z value (4D waves only).
V_maxChunkLoc	Chunk containing maximum Z value (4D waves only).
V_startRow	First wave point. Zero if you do not use /R.
V_endRow	Last wave point. Last point if you do not use /R.

WaveStats prints the statistics in the history area unless /Q is specified. The various multidimensional min and max location variables will only print to the history area for waves having the appropriate dimensionality.

The format of the M\_WaveStats wave is:

Row	Statistic	Row	Statistic	Row	Statistic
0	numPoints	9	minLoc	18	maxColLoc
1	numNaNs	10	min	19	maxLayerLoc
2	numInfs	11	maxLoc	20	maxChunkLoc
3	avg	12	max	21	startRow
4	sdev	13	minRowLoc	22	endRow
5	rms	14	minColLoc	23	sum
6	adev	15	minLayerLoc	24	meanL1

## WaveTransform

Row	Statistic	Row	Statistic	Row	Statistic
7	skew	16	minChunkLoc	25	meanL2
8	kurt	17	maxRowLoc		

meanL1 and meanL2 are the confidence intervals for the mean

$$MeanL1 = V\_avg - t_{\alpha,v} \frac{V\_sdev}{\sqrt{V\_npnts}} \text{ and } MeanL2 = V\_avg + t_{\alpha,v} \frac{V\_sdev}{\sqrt{V\_npnts}}$$

where  $t_{\alpha,v}$  is the critical value of the Student T distribution for  $\alpha$  significance and degree of freedom  $v=V\_npnts-1$ .

Use `Edit M_WaveStats.1d` to display the results in a table with dimension labels identifying each of the row statistics.

WaveStats is not entirely multidimensional aware. Even so, much of the information computed by WaveStats is useful. See **Analysis on Multidimensional Waves** on page II-94 for details.

## WaveTransform

### WaveTransform [ flags ] keyword srcWave

The WaveTransform operation transforms *srcWave* in various ways. If the /O flag is not specified then unless otherwise indicated the output is stored in the wave `W_WaveTransform`, which will be of the same data type as *srcWave* and saved in the current data folder.

### Parameters

*keyword* is one of the following:

abs	Calculates the absolute value of the entries in <i>srcWave</i> . It stores results in <code>W_Abs</code> if <i>srcWave</i> is 1D or <code>M_Abs</code> otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. <i>srcWave</i> must be single or double precision real wave.
acos	Calculates the inverse cosine of the entries in <i>srcWave</i> . It stores results in <code>W_Acos</code> if <i>srcWave</i> is 1D or <code>M_Acos</code> otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. <i>srcWave</i> must be single or double precision real wave.
asin	Calculates the inverse sine of the entries in <i>srcWave</i> . It stores results in <code>W_Asin</code> if <i>srcWave</i> is 1D or <code>M_Asin</code> otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. <i>srcWave</i> must be single or double precision real wave.
atan	Calculates the inverse tangent of the entries in <i>srcWave</i> . It stores results in <code>W_Atan</code> if <i>srcWave</i> is 1D or <code>M_Atan</code> otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. <i>srcWave</i> must be single or double precision real wave.
cconjugate	Calculates the complex conjugate of <i>srcWave</i> . Stores results in <code>W_CConjugate</code> or <code>M_CConjugate</code> , depending on wave dimensionality, or overwrites <i>srcWave</i> if /O is used.
cos	Calculates the cosine of the entries in <i>srcWave</i> . It stores results in <code>W_Cos</code> if <i>srcWave</i> is 1D or <code>M_Cos</code> otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. <i>srcWave</i> must be single or double precision real wave.
crystalToRect	Converts triplet (three column {x,y,z}) waves from nonorthogonal crystallographic coordinates to rectangular cartesian system. The parameters provided in the /P flag are the crystallographic definition of the coordinate system given by {a, b, c, alpha, beta, gamma}. The three angles are assumed to be expressed in radians unless the /D flag is specified. The transformation sets the first component parallel to the vector a and the third component parallel to $c^*$ . The output is stored in the current data folder in the wave <code>M_CrystalToRect</code> which has the same data type. If the /O flag is specified, the output overwrites the original data.
flip	Flips the data in <i>srcWave</i> about its center. If /O flag is used, <i>srcWave</i> is overwritten. Otherwise a new wave is created in the current data folder. The wave is named <code>W_flipped</code> or <code>M_flipped</code> according to the dimensionality of <i>srcWave</i> .

---

index	Fills <i>srcWave</i> as in <code>jack=p</code> . If /P is specified then <code>jack=p+param1</code> . The /O flag does not apply here.
inverse	Computes $1/srcWave[i]$ for each point in <i>srcWave</i> and stores it in <code>W_Inverse</code> or <code>M_Inverse</code> depending on the dimensionality of <i>srcWave</i> .
inverseIndex	Fills <i>srcWave</i> as in <code>jack=numPnts-1-p</code> . If /P is specified the <code>jack=numPnts-1-p+param1</code> .
magnitude	Creates a real-valued wave that is the magnitude of <i>srcWave</i> . If you do not specify the /O flag, the output is stored in <code>W_Magnitude</code> or <code>M_Magnitude</code> depending on the dimensionality of <i>srcWave</i> ; the output precision will be the same as <i>srcWave</i> .
magsqr	Creates a real-valued wave that is the magnitude squared of <i>srcWave</i> . If <i>srcWave</i> is a double precision complex wave, the output is also double precision, otherwise the output is a single precision wave. Stores the result in wave <code>W_MagSqr</code> or <code>M_MagSqr</code> , depending on the dimensionality of <i>srcWave</i> , or overwrites <i>srcWave</i> if /O is used.
max	Calculates the maximum of a point in <i>srcWave</i> and a fixed number specified as a single parameter with the /P flag. It stores results in <code>W_max</code> if <i>srcWave</i> is 1D or <code>M_max</code> otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. See also the <code>max</code> keyword and examples.
min	Calculates the minimum of a point in <i>srcWave</i> and a fixed number specified as a single parameter with the /P flag. It stores results in <code>W_min</code> if <i>srcWave</i> is 1D or <code>M_min</code> otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. See also the <code>max</code> keyword and examples.
normalizeArea	Calculates the area under the curve and rescales the wave so that the area is 1. Note that waves with negative areas will be rescaled to positive values. Applies to 1D real-valued waves. It does not affect wave scaling. Stores the result in the wave <code>W_normalizedArea</code> or overwrites <i>srcWave</i> if /O is used.
phase	Creates a real-valued wave containing the phase of the complex input wave. If the /O flag is not used, the output is stored in <code>W_Phase</code> or <code>M_Phase</code> depending on the dimensionality of <i>imageMatrix</i> . You can also use <code>/P={norm}</code> to divide the output wave by the value of <i>norm</i> .
rectToCrystal	Converts triplet (three column {x,y,z}) waves from cartesian coordinates to nonorthogonal crystallographic coordinate system. The parameters provided in the /P flag are the crystallographic definition of the coordinate system given by {a, b, c, alpha, beta, gamma}. The three angles are assumed to be expressed in radians unless the /D flag is specified. The transformation assumes the first component parallel to the vector a and the third component parallel to c*. The output is stored in the current data folder in the wave <code>M_RectToCrystal</code> which has the same data type. If the /O flag is specified, the output overwrites the original data.
sgn	Sets the value to -1 if the entry is negative, 1 otherwise. Stores the results in <code>W_Sgn</code> or overwrites <i>srcWave</i> if /O is used. This operation will not work on UNSIGNED waves.
shift	Shifts the position of data in <i>srcWave</i> by the specified number of points. Unlike Rotate, WaveTransform discards data points that shift outside existing wave boundaries. After the shift, vacated wave points are set to the specified <i>fillValue</i> . The shift and the <i>fillValue</i> are specified with the /P flag using the syntax: <code>/P={numPoints,fillValue}</code> . If you do not provide a fill value, it will be 0 for integer waves and NaN for SP and DP.
sqrt	Calculates the square root of the entries in <i>srcWave</i> . It stores results in <code>W_sqrt</code> if <i>srcWave</i> is 1D or <code>M_sqrt</code> otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. <i>srcWave</i> must be single- or double-precision real wave.
tan	Calculates the tangent of the entries in <i>srcWave</i> . The results are stored in <code>W_tan</code> if <i>srcWave</i> is 1D or <code>M_tan</code> otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. <i>srcWave</i> must be single- or double-precision real wave.
<b>Flags</b>	
/D	Specifies that angles are in degrees.
/O	Overwrites input wave.

## WaveType

---

`/P={param1...}` Specifies parameters as appropriate for the keyword that you are using. The number of parameters and their order depends on the keyword.

### Examples

Produce output values in the range [-1,1]:

```
Wavetransform /P={pi} phase complexWave
```

```
WaveTransform /P={1}/O min myWave // faster than myWave=myWave>1 ? 1 : myWave
```

### See Also

The **Rotate** operation.

### References

Shmueli, U. (Ed.), International Tables for Crystallography, Volume B: 3.3, Kluwer Academic Publishers, Dordrecht, The Netherlands, 1996.

## WaveType

### **WaveType**(*waveName*)

The WaveType function returns the type of data stored in the wave.

The returned value will be zero for a text wave. Numeric waves will return a combination of bit values:

Type	Bit Number	Decimal Value	Hexadecimal Value
complex	0	1	1
32-bit float	1	2	2
64-bit float	2	4	4
8-bit integer	3	8	8
16-bit integer	4	16	10
32-bit integer	5	32	20
unsigned	6	64	40

The unsigned bit is used only with the integer types while the complex bit can be used with any. Only one of the bits 1-5 are set at a time. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

### Examples

```
Variable waveIsComplex = WaveType(wave) & 0x01  
Variable waveIs32BitFloat = WaveType(wave) & 0x02  
Variable waveIs64BitFloat = WaveType(wave) & 0x04  
Variable waveIs8BitInteger = WaveType(wave) & 0x08  
Variable waveIs16BitInteger = WaveType(wave) & 0x10  
Variable waveIs32BitInteger = WaveType(wave) & 0x20  
Variable waveIsUnsigned = WaveType(wave) & 0x40
```

## WaveUnits

### **WaveUnits**(*waveName*, *dimNumber*)

The WaveUnits function returns a string containing the units for the given dimension.

Use *dimNumber*=0 for rows, 1 for columns, 2 for layers, and 3 for chunks. Use -1 to get the data units. If the wave is just 1D, *dimNumber*=0 returns X units and 1 returns data units. This behavior is just like the WaveMetrics procedure WaveUnits found in the WaveMetrics Procedures folder in previous versions of Igor Pro.

## wfprintf

**wfprintf** *refNum*, *formatStr* [*flags*] *waveName* [, *waveName*]...

The `wfprintf` operation is like `printf` except that it prints the contents of the named waves to a file whose file reference number is in *refNum*.

The `Save` operation also outputs wave data to a text file. Use `Save` unless you need the added flexibility provided by `wfprintf`.

### Parameters

*refNum* is a file reference number from the `Open` operation used to create the file.

The value of each named wave is printed to the file according to the conversion specified in *formatStr*.

*formatStr* contains one numeric conversion specification per column. See `printf`. If *formatStr* is "", `wfprintf` uses a default format which gives tab-delimited columns.

### Flags

`/R=(startX,endX)` Specifies an X range in the wave(s) to print.

`/R=[startP,endP]` Specifies a point range in the wave(s) to print.

If you use the `/R` flag, you must not put a comma between format and `/R`.

### Details

A complex wave in the wavelist is treated as two separate columns and requires two separate conversion specifications if you do not use the default "" specification.

The number of conversion characters must exactly match the number of columns (one column per real wave, two columns per complex wave) in the wave list. The wave list is limited to 100 waves. You can output up to 200 columns by using complex waves instead of real waves.

The only conversion characters allowed are: `fFeEgdouxXc` (the floating point and integer conversion characters). You cannot use an asterisk to specify field width or precision.

If any of these restrictions is intolerable, you can use `fprintf` in a loop.

The `wfprintf` operation is not multidimensional aware. See [Analysis on Multidimensional Waves](#) on page II-94 for details.

The `wfprintf` operation supports numeric (real only) and string fields from structures. All other field type will cause a compile error.

### See Also

The `printf` operation for complete format and parameter descriptions and [Creating Formatted Text](#) on page IV-184. The `Open` operation about *refNum* and for another way of writing wave files.

The `Save` operation.

## WhichListItem

**WhichListItem**(*itemStr*, *listStr* [, *listSepStr* [, *startIndex* [, *matchCase*]])

The `WhichListItem` function returns the index of the first item of *listStr* that matches *itemStr*. *listStr* should contain items separated by the *listSepStr* character, such as "abc;def;". If the item is not found in the list, -1 is returned.

Use `WhichListItem` to locate an item in a string containing a list of items separated by a single character, such as those returned by functions like `TraceNameList` or `AnnotationList`, or a line from a delimited text file.

*listSepStr*, *startIndex*, and *matchCase* are optional; their defaults are ";", 0, and 1 respectively.

### Details

`WhichListItem` differs from `FindListItem` in that `WhichListItem` returns a list index, while `FindListItem` returns a character offset into a string.

*listStr* is searched for *itemStr* bound by *listSepStr* on the left and right.

*listStr* is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *listSepStr* are always case-sensitive. The comparison of *itemStr* to the contents of *listStr* is usually case-sensitive. Setting the optional *matchCase* parameter to 0 makes the comparison case insensitive.

## WignerTransform

---

If *itemStr* is not found, if *listStr* is "", or if *startIndex* is not within the range of 0 to `ItemsInList(listStr)-1`, then -1 is returned.

Only the first character of *listSepStr* is used.

Items can be empty. The lists "abc;def;;ghi" and ";abc;def;;ghi;" have four items (the third item is ""). Use `WhichListItem("", listStr)` to find the first empty item.

If *startIndex* is specified, then *listSepStr* must also be specified. If *matchCase* is specified, *startIndex* and *listSepStr* must be specified.

### Examples

```
Print WhichListItem("wave0", "wave0;wave1;") // prints 0
Print WhichListItem("c", "a;b;") // prints -1
Print WhichListItem("", "a;b;") // prints 1
Print WhichListItem("c", "a,b,c,x,c", ",") // prints 2
Print WhichListItem("c", "a,b,c,x,c", ",", 3) // prints 4
Print WhichListItem("C", "x;c;C;") // prints 2
Print WhichListItem("C", "x;c;C;", ";", 0, 0) // prints 1
```

The `AddListItem`, `FindListItem`, `FunctionList`, `ItemsInList`, `RemoveFromList`, `RemoveListItem`, `StringFromList`, `StringList`, `TraceNameList`, `VariableList`, and `WaveList` functions.

## WignerTransform

**WignerTransform** [/Z][/WIDE=*wSize*][/GAUS=*gaussianWidth*][/DEST=*destWave*] *srcWave*

The WignerTransform operation computes the Wigner transformation of a 1D signal in *srcWave*, which is the name of a real or complex wave. The result of the WignerTransform is stored in *destWave* or in the wave `M_Wigner` in the current data folder.

### Flags

- /DEST=*destWave* Creates by default a real wave reference for the destination wave in a user function. See **Automatic Creation of WAVE References** on page IV-53 for details.
- /GAUS=*gWidth* Computes the Gaussian Wigner Transform, which is a convolution of the Wigner Transform with a two-dimensional Gaussian (in the two parameters of the transform). The computation of the transform simplifies significantly when the product of the widths of the two Gaussians is unity (minimum uncertainty ellipse).  
*gWidth* uses the same units as the *srcWave* scaling.
- /WIDE=*wSize* Computes Wigner Transform and sets the transform width to *wSize*. This is the default transformation with *wSize* set to the size of *srcWave*.
- /Z No error reporting.

### Details

The Wigner transform maps a time signal  $U(t)$  into a 2D time-frequency representation:

$$W(t,\nu) = \int_{-\infty}^{\infty} U\left(t + \frac{x'}{2}\right) U^*\left(t - \frac{x'}{2}\right) e^{-2\pi i x' \nu} dx'.$$

The computation of the Wigner transform evaluates the offset product

$$U\left(t + \frac{x'}{2}\right) U^*\left(t - \frac{x'}{2}\right)$$

over a finite window and then Fourier transforms the result. The offset product can be evaluated over a finite window width, which can vary from a few elements of the input wave to the full length of the wave. You can control the width of this window using the /WIDE flag. If you do not specify the output destination, WignerTransform saves the results in the wave `M_Wigner` in the current data folder.

The input wave can be of any numeric data type, and the output data type and precision will be the same as the input. Although the Wigner transform is real, the output will be complex when *srcWave* is complex. By inspecting the complex wave you can gain some insight into the numerical stability of the algorithm. The X-scaling of the output wave is identical to the scaling of *srcWave*. The Y-scaling of the input wave is taken from the Fourier Transform of the offset product, which in turn is determined by the X-scaling of

*srcWave*. Specifically, if  $dx = \text{DimDelta}(srcWave, 0)$  and *srcWave* has N points then  $dy = \text{DimDelta}(M\_Wigner, 1) = 1 / (dx * N)$ . WignerTransform does not set the units of the output wave. The Ambiguity Function is related to the Wigner Transform by a Fourier Transform, and is defined by

$$A(\tau, \nu) = \int_{-\infty}^{\infty} U\left(t + \frac{\tau}{2}\right) U^*\left(t - \frac{\tau}{2}\right) e^{-2\pi i t \nu} dt.$$

Convolving the Wigner Transform with a 2D Gaussian leads to what is sometimes called the Gaussian Wigner Transform or GWT. Formally the GWT is given by the equation:

$$GWT(t, \nu; \delta_t, \delta_\nu) = \frac{1}{\delta_t \delta_\nu} \iint dt' dv' W(t', \nu') e^{-2\pi \left(\frac{t-t'}{\delta_t}\right)^2} e^{-2\pi \left(\frac{\nu-\nu'}{\delta_\nu}\right)^2}.$$

Computationally this equation simplifies if the respective widths of the two Gaussians satisfy the minimum uncertainty condition  $\delta_t^* \delta_\nu = 1$ . The /Gaus flag calculates the Gaussian Wigner Transform using your specified width,  $\delta_t$ , and it selects a  $\delta_\nu$  such that it satisfies the minimum uncertainty condition.

## Window

**Window** *macroName*([*parameters*]) [:*macro type*]

The Window keyword introduces a macro that recreates a graph, table, layout, or control panel window. The macro appears in the appropriate submenu of the Windows menu. Window macros are automatically created when you close a graph, table, layout, control panel, or XOP target window (e.g., surface plot). You should use **Macro**, **Proc**, or **Function** instead of Window for your own window macros. Otherwise, it works the same as **Macro**.

#### See Also

The **Macro**, **Proc**, and **Function** keywords. **Data Folders and Window Macros** on page II-109 for details.

**Macro Syntax** on page IV-80 for further information.

## WindowFunction

**WindowFunction** [/FFT[=*f*] /DEST=*destWave*] *windowKind*, *srcWave*

The WindowFunction operation multiplies a one-dimensional (real or complex) *srcWave* by the named window function.

By default the result overwrites *srcWave*.

#### Parameters

*srcWave*

A one-dimensional wave of any numerical type. See **ImageWindow** for windowing two-dimensional data.

*windowKind*

Specifies the windowing function, which are listed in bold (some windows, in italics, have multiple options for different constant values). The equations assume that /FFT=1:

**Bartlett:** a synonym for Bartlett.

$$\text{Bartlett: } w(n) = \begin{cases} \frac{n}{N/2} & n = 0, 1, \dots, \frac{N}{2} \\ W(N-n) & n = \frac{N}{2}, \dots, N-1 \end{cases}.$$

## WindowFunction

---

*Blackman:*  $w(n) = a_0 - a_1 \cos\left(\frac{2\pi}{N}n\right) + a_2 \cos\left(\frac{2\pi}{N}2n\right) - a_3 \cos\left(\frac{2\pi}{N}3n\right)$  .  
 $n = 0, 1, 2, \dots, N-1$

<i>windowKind</i>	$a_0$	$a_1$	$a_2$	$a_3$
<b>Blackman367</b>	0.42323	0.49755	0.07922	
<b>Blackman361</b>	0.44959	0.49364	0.05677	
<b>Blackman492</b>	0.35875	0.48829	0.14128	0.01168
<b>Blackman474</b>	0.40217	0.49703	0.09392	0.00183

*Cos:*  $w(n) = \cos\left(\frac{n}{N}\pi\right)^\alpha$   $n = -\frac{N}{2}, \dots, -1, 0, 1, \dots, \frac{N}{2}$

**Cos1:**  $\alpha = 1.$

**Cos2:**  $\alpha = 2.$

**Cos3:**  $\alpha = 3.$

**Cos4:**  $\alpha = 4.$

**Hamming:**  $w(n) = \begin{cases} 0.54 + 0.46 \cos\left(\frac{2\pi}{N}n\right) & n = -\frac{N}{2}, \dots, -1, 0, 1, \dots, \frac{N}{2} \\ 0.54 - 0.46 \cos\left(\frac{2\pi}{N}n\right) & n = 0, 1, 2, \dots, N-1 \end{cases}$  .

**Hanning:**  $w(n) = \begin{cases} \frac{1}{2} \left[ 1 + \cos\left(\frac{2n}{N}\pi\right) \right] & n = -\frac{N}{2}, \dots, -1, 0, 1, \dots, \frac{N}{2} \\ \frac{1}{2} \left[ 1 - \cos\left(\frac{2n}{N}\pi\right) \right] & n = 0, 1, 2, \dots, N-1 \end{cases}$  .

*Kaiser Bessel:*  $w(n) = \frac{I_0\left(\pi\alpha \sqrt{1 - \left(\frac{n}{N/2}\right)^2}\right)}{I_0(\pi\alpha)}$   $0 \leq |n| \leq \frac{N}{2}$  .

$$I_0(X) = \sum_{k=0}^{\infty} \left( \frac{(x/2)^{2k}}{k!} \right)^2$$

**KaiserBessel20:**  $\alpha = 2.$

**KaiserBessel25:**  $\alpha = 2.5.$

**KaiserBessel30:**  $\alpha = 3.$

**Parzen:**  $w(n) = 1 - \left| \frac{n}{N/2} \right|^2$   $0 \leq |n| \leq \frac{N}{2}$  .

*Poisson:*  $w(n) = \exp\left(-\alpha \frac{|n|}{N/2}\right)$   $0 \leq |n| \leq \frac{N}{2}$  .

**Poisson2:**  $\alpha = 2.$

**Poisson3:**  $\alpha = 3.$

**Poisson4:**  $\alpha = 4.$

**Riemann:**  $w(n) = \frac{\sin\left(\frac{n}{N}2\pi\right)}{\left(\frac{n}{N}2\pi\right)}$   $0 \leq |n| \leq \frac{N}{2}$  .

**Flags**

`/DEST=destWave` Creates or overwrites *destWave* with the result of the multiplication of *srcWave* and the window function.

When used in a function, the WindowFunction operation by default creates a real wave reference for the destination wave. See **Automatic Creation of WAVE References** on page IV-53 for details.

`/FFT [=1]`

The window interval is  $0 \dots N = \text{numpts}(\text{srcWave})$ . This sets the first value of *srcWave* to zero, but not the last value. This is appropriate for windowing data in preparation for Fourier Transforms, and is the same algorithm used by FFT.

The window interval is  $0 \dots N = \text{numpts}(\text{srcWave}) - 1$  if /FFT is missing or /FFT=0. This sets the first and last value of *srcWave* to 0. This is the (only) algorithm that the Hanning operation uses.

**Details**

A "window function" alters the input data by decreasing values near the start and end of the data smoothly towards zero, so that when the FFT of the data is computed the effects of nonintegral-periodic signals are diminished. This improves the ability of the FFT to distinguish among closely-spaced frequencies. Each window function has advantages and disadvantages, usually trading off rejection of "leakage" against the ability to discriminate adjacent frequencies. For more details, see the **References**.

WindowFunction stores the window function's normalization value (the average squared window value) in `V_value`. This is the value you would get from WaveStats's `V_rms*V_rms` for a wave of *srcWave*'s length whose values were all equal to 1:

```
Make/O data = 1
WindowFunction Bartlett, data // Bartlett allowed as synonym for Bartlett
Print V_value // Prints 0.330709, mean of squared window values
```

```
WaveStats/Q data
Print V_rms*V_rms // Prints 0.330709
```

**See Also**

FFT and ImageWindow operations.

**References**

For more information about the use of window functions see:

Harris, F.J., On the use of windows for harmonic analysis with the discrete Fourier Transform, *Proc, IEEE*, 66, 51-83, 1978.

Wikipedia entry: <[http://en.wikipedia.org/wiki/Window\\_function](http://en.wikipedia.org/wiki/Window_function)>.

**WinList****WinList(*matchStr*, *separatorStr*, *optionsStr*)**

The WinList function returns a string containing a list of windows selected based on the *matchStr* and *optionsStr* parameters.

**Details**

For a window name to appear in the output string, it must match *matchStr* and also must fit the requirements of *optionsStr*. The first character of *separatorStr* is appended to each window name as the output string is generated.

The name of each window is compared to *matchStr*, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

```
"*"      Matches all window names
"xyz"    Matches window name xyz only
"*xyz"   Matches window names which end with xyz
```

## WinList

---

"xyz\*" Matches window names which begin with xyz  
"\*xyz\*" Matches window names which contain xyz  
"abc\*xyz" Matches window names which begin with abc and end with xyz

*matchStr* may begin with the ! character to return windows that do not match the rest of *matchStr*. For example:

"!\*xyz" Matches window names which *do not* end with xyz

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of *matchStr*.

*optionsStr* is used to further qualify the window. The acceptable values for *optionsStr* are:

" "	Consider all windows.
"WIN:"	The target window.
"WIN: <i>windowTypes</i> "	Consider windows that match <i>windowTypes</i> .
"INCLUDE: <i>includeTypes</i> "	Consider procedure windows that match <i>includeTypes</i> .
"INDEPENDENTMODULE:1"	If <code>SetIgorOption independentModuleDev=1</code> , then consider procedure windows that are part of any independent module.
	If <code>SetIgorOption independentModuleDev=0</code> or if <code>INDEPENDENTMODULE:0</code> , then procedure windows that are part of any independent module are not listed.

*windowTypes* is a literal number. The window name goes into the output string only if it passes the match test and its type is compatible with *windowTypes*. *windowTypes* is one of:

- 1: Graphs.
- 2: Tables.
- 4: Layouts.
- 16: Notebooks.
- 64: Panels.
- 128: Procedure windows.
- 4096: XOP target windows (e.g., surface plots).

or a bitwise combination of the above for more than one type of inclusion. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

Procedure windows don't have names. WinList returns the procedure window title instead.

*includeTypes* is also a literal number. The window name goes into the output string only if it passes the match test and its type is compatible with *includeTypes*. *includeTypes* is one of:

- 1: Procedure windows that are not #included.
- 2: Procedure windows included by `#include "someFileName"`.
- 4: Procedure windows included by `#include <someFileName>`.

or a bitwise combination of the above for more than one type of inclusion.

You can combine the WIN, INCLUDE and INDEPENDENTMODULE options by separating them with a comma.

When executing `SetIgorOption independentModuleDev=1` after opening the current experiment, the title of any procedure window in an independent module will be followed by [*nameOfIndependentModule*].

For example, if a procedure file contains:

```
#pragma IndependentModule=myIndependentModule  
#include <Axis Utilities>
```

A call to WinList like this:

```
String procedureWindows = WinList("*, ";, "WIN:128,INCLUDE:8")
```

will store "Axis Utilities.ipf [myIndependentModule];" into the procedureWindows string, along with any other procedure windows that are part of that independent module. The procedure window that contains the

```
#pragma IndependentModule=myIndependentModule
```

statement is also listed with the independent module name.

To get a list of procedure windows that comprise a particular independent module, you can use a call such as:

```
SetIgorOption IndependentModuleDev=1  
list= WinList("* [myIndependentModule] ", ";", "WIN:128,INDEPENDENTMODULE:1")
```

**Examples**

Command	Returned List
<code>WinList("*", ";", "")</code>	All existing windows.
<code>WinList("*", ";", "WIN:3")</code>	All graph and table windows.
<code>WinList("Result_*", ";", "WIN:1")</code>	Graphs whose names start with "Result_".
<code>WinList("*", ";", "INCLUDE:6")</code>	All #included procedure windows.
<code>WinList("*", ";", "WIN:1, INCLUDE:6")</code>	All graphs and #included procedure windows.

**See Also**

The **IndependentModule Pragma** on page IV-40. The **ChildWindowList** and **WinType** functions.

**WinName**

**WinName(index, windowTypes [, visibleWindowsOnly])**

The WinName function returns a string containing the name of the *index*th window of the specified *type*, or the null string ("") if no window fits the parameters.

If the optional *visibleWindowsOnly* is nonzero, only visible windows are considered (the default is both visible and hidden windows).

Procedure windows don't have names. WinName returns the procedure window title instead.

**Details**

*index* starts from zero, and returns the top-most window matching the parameters.

The window names are ordered in window-stacking order, as returned by WinList.

**DoWindow/B** moves the window to the back and changes the index needed to retrieve its name to the greatest index that returns any name.

Hiding or showing a window (with **SetWindow hide=1** or **Notebook visible=0** or by manual means) does not affect the index associated with the window.

*windowTypes* is one of:

- 1: Graphs.
- 2: Tables.
- 4: Layouts.
- 16: Notebooks.
- 64: Panels.
- 128: Procedure windows.
- 4096: XOP target windows (e.g., surface plots).

or a bitwise combination of the above for more than one type of window. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

**Examples**

```
Print WinName(0,1)           // Prints the name of the top graph.
Print WinName(0,3)           // Prints the name of the top graph or table.
String win=WinName(0,1)      // The name of the top visible graph.
SetWindow $win hide=1       // Hide the graph (it may already be hidden).
Print WinName(0,1)           // Prints the name of the now-hidden graph.
Print WinName(0,1,1)        // Prints the name of the top visible graph.
```

**See Also**

The **WinList**, **DoWindow** (/F and /B flags), **SetWindow** (hide keyword), and **Notebook** (Miscellaneous) (visible keyword) operations.

### WinRecreation

#### **WinRecreation(winNameStr, options)**

The WinRecreation function returns a string containing the window recreation macro (or style macro) for the named window.

#### **Details**

If *winNameStr* is "", the macro for the top graph, table, page layout, panel, notebook, or XOP target window is returned.

If *options* is 0, WinRecreation returns the window recreation macro.

If *options* is 1, WinRecreation returns the style macro or an empty string if the window does not support style macros.

#### **Graphs Details**

If *options* is 2, WinRecreation returns a recreation macro in which all occurrences of wave names are replaced with an ID number having the form ##<number>## (for instance, ##25##). These ID numbers can be found easily using the **strsearch** function. This is intended for applications that need to alter the recreation macro by replacing wave names with something else, usually other wave names. The ID numbers are the same as those returned by the **GetWindow** operation with the wavelist keyword.

#### **Graphs and Panels Details**

If *options* is 4, WinRecreation returns the window recreation macro without the default behavior of causing the graph to revert to "normal" mode (as if the GraphNormal operation had been called). This allows the use of WinRecreation when a graph or panel is in drawing tools mode without exiting that mode. For windows other than graphs or panels, this is equivalent to an *options* value of 0.

#### **Notebooks Details**

If *options* is -1, WinRecreation returns the same text that the Generate Commands menu item would generate with the Selected paragraphs radio button selected and all the checkboxes selected (includes text commands).

If *options* is 0, WinRecreation returns the same text that the Generate Commands menu item would generate with the Entire document radio button selected and all the checkboxes *except* "Generate text commands" selected).

If *options* is 1, WinRecreation returns the same text that the Generate Commands menu item would generate with the Entire document radio button selected and all the checkboxes selected (includes text commands).

Regardless of the value of *options* the text returned by WinRecreation for notebook always ends with 5 lines of file-related information formatted as comments:

```
// File Name: MyNotebook.txt
// Path: "Macintosh HD:Desktop Folder:"
// Symbolic Path: home
// Selection Start: paragraph 100, position 31
// Selection End: paragraph 100, position 31
```

#### **Examples**

```
WinRecreation("Graph0",0)           // Returns recreation macro for Graph0.
WinRecreation("",1)                 // Style macro for top window.
String win= WinName(0,16,1)         // top visible notebook
String str= WinRecreation(str,-1)    // Selected Text commands
Variable line= itemsInList(str,"\r")-5 // First file info line
Print StringFromList(line, str,"\r") // Print File Name:
Print StringFromList(line+1, str,"\r") // Print Path:
Print StringFromList(line+2, str,"\r") // Print Symbolic Path:
Print StringFromList(line+3, str,"\r") // Selection Start:
Print StringFromList(line+4, str,"\r") // Selection End:
```

#### **See Also**

**Saving a Window as a Recreation Macro** on page II-51.

## WinType

### WinType(*winNameStr*)

The WinType function returns a value indicating the type of the named window.

#### Details

*winNameStr* is a string or string expression containing the name of a window or subwindow, or "" to signify the target window. When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

WinType returns the following values:

- 0: No window by that name.
- 1: Graph.
- 2: Table.
- 3: Layout.
- 5: Notebook.
- 7: Panel.
- 13: XOP target window (e.g., surface plot).

Because command and procedure windows do not have *names* (they only have *titles*), WinType can not even be asked about those windows.

#### See Also

The **WinName**, **ChildWindowList**, and **WinList** functions.

## wnoise

### wnoise(*shape*, *scale*)

The wnoise function returns a pseudo-random value from the two-parameter Weibull distribution characterized by the *shape* and *scale*, the respective *g* and *a* parameters. The two-parameter Weibull probability distribution function is

$$f(x, \alpha, \gamma) = \frac{\gamma}{\alpha} \left(\frac{x}{\alpha}\right)^{\gamma-1} \exp\left[-\left(\frac{x}{\alpha}\right)^\gamma\right] \quad \begin{array}{l} x \geq 0 \\ \gamma > 0 \\ \alpha > 0 \end{array}$$

The mean of the Weibull distribution is

$$\alpha^\gamma \Gamma\left(1 + \frac{1}{\gamma}\right)$$

and the variance is

$$\alpha^\gamma \Gamma\left(1 + \frac{2}{\gamma}\right) - \alpha^\gamma \left[\Gamma\left(1 + \frac{1}{\gamma}\right)\right]^2$$

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; **SetRandomSeed**.

## x

### x

The x function returns the scaled row index for the current point of the destination wave in a wave assignment statement. This is the same as the X value if the destination wave is a vector (1D wave).

## x2pnt

---

### Details

Outside of a wave assignment statement, *x* acts like a normal variable. That is, you can assign a value to it and use it in an expression.

### See Also

The *p* function and **Waveform Arithmetic and Assignments** on page II-80.

## x2pnt

### **x2pnt**(*waveName*, *x1*)

The *x2pnt* function returns the point number on the wave whose X value is closest to *x1*.

### Details

There are no equivalent functions for multidimensional waves. To calculate this information for other dimensions, use this expression:

$(ScaledDimPos - DimOffset(waveName, dim)) / DimDelta(waveName, dim)$

This expression calculates the number of an element in the dimension *dim* (*p*, *q*, *r*, or *s*). *ScaledDimPos* is the scaled position in that dimension (*x*, *y*, *z*, or *t*). *dim* is 0 for rows, 1 for columns, 2 for layers or 3 for chunks. Setting *dim* = 0 is equivalent to using *x2pnt*. The point number includes a fractional part; you may wish to use **ceil**, **round**, **trunc**, or **floor** to calculate an integer point number.

### See Also

The functions **DimDelta**, and **DimOffset**.

For an explanation of waves and X scaling, see **Changing Dimension and Data Scaling** on page II-70.

## xcsr

### **xcsr**(*cursorName* [, *graphNameStr*])

The *xcsr* function returns the X value of the point which the named cursor (A through J) is on in the top or named graph.

### Parameters

*cursorName* identifies the cursor, which can be cursor A through J.

*graphNameStr* specifies the graph window or subwindow.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

### Details

The result is derived from the wave that the cursor is on, not from the X axis of the graph. If the wave is displayed as an XY pair, the X axis and the wave's X scaling will usually be different.

### See Also

The **Cursor** operation and the **CsrInfo**, **hcsr**, **pcsr**, **qcsr**, **vcscr**, and **zcscr** functions.

## XWaveName

### **XWaveName**(*graphNameStr*, *waveNameStr*)

The *XWaveName* function returns a string containing the name of the wave supplying the X coordinates against which the named wave is displayed in the named graph window or subwindow.

### Parameters

*graphNameStr* can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

### Details

*XWaveName* returns the null string ("" ) if the wave is not plotted versus an X wave.

For most uses, we recommend that you use **XWaveRefFromTrace** instead of *WaveName*. *XWaveName* returns a string containing the wave name only, with no data folder path qualifying it. Thus, you may get erroneous results if the X wave referred to in the graph has the same name as a different wave in the current

data folder. Likewise, if the named wave resides in a folder that is not the current data folder, you will not be able to refer to the named wave.

*graphNameStr* and *waveNameStr* are strings, *not* names.

### Examples

```
Display ywave vs xwave           // XY graph
Print XWaveName("", "ywave")     // prints xwave
```

## XWaveRefFromTrace

### **XWaveRefFromTrace**(*graphNameStr*, *traceNameStr*)

The XWaveRefFromTrace function returns a wave reference to the wave supplying the X coordinates against which the named trace is displayed in the named graph window or subwindow.

### Parameters

*graphNameStr* can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

### Details

XWaveRefFromTrace returns a null reference (see **WaveExists**) if the wave is not plotted versus an X wave.

*graphNameStr* and *traceNameStr* are strings, *not* names.

### Examples

```
Display ywave vs xwave           // XY graph
Print XWaveRefFromTrace("", "ywave")[50] // prints value of xwave at point 50
```

For commands referencing other waves in a graph: **ImageNameList**, **ImageNameToWaveRef**, **ContourNameList**, and **ContourNameToWaveRef**.

For a discussion of wave references, see **Wave Reference Functions** on page IV-143.

## y

### y

The y function returns the Y value for the current column of the destination wave when used in a multidimensional wave assignment statement. Y is the scaled column index whereas **q** is the column index itself.

### Details

Unlike **x**, outside of a wave assignment statement, y does not act like a normal variable.

### See Also

**x**, **z**, and **t** functions for other dimensions.

**p**, **q**, **r**, and **s** functions for the scaled indices.

## Z

### z

The z function returns the Z value for the current layer of the destination wave when used in a multidimensional wave assignment statement. z is the scaled layer index whereas **r** is the layer index itself.

### Details

Unlike **x**, outside of a wave assignment statement, z does not act like a normal variable.

### See Also

**x**, **y**, and **t** functions for other dimensions.

**p**, **q**, **r**, and **s** functions for the scaled indices.

**ZCSR****zcsr(cursorName [ , graphNameStr])**

The **zcsr** function returns a Z value when the specified cursor is on a contour, image, or waterfall plot. Otherwise, it returns NaN.

**Parameters**

*cursorName* identifies the cursor, which can be cursor A through J.

*graphNameStr* specifies the graph window or subwindow.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**Examples**

```
Print zcsr(A)           // not zcsr("A")
Print zcsr(A,"Graph0") // specifies the graph
```

**See Also**

The **Cursor** operation and the **CsrInfo**, **hcsr**, **pcsr**, **qcsr**, **vcscr**, and **xcscr** functions.

**ZernikeR****zernikeR(n, m, r)**

The **ZernikeR** function returns the Zernike radial polynomials of degree  $n$  that contains no power of  $r$  that is less than  $m$ . Here  $m$  is even or odd according to whether  $n$  is even or odd, and  $r$  is in the range 0 to 1.

Note that the full circle polynomials are complex. For any angle  $t$  (theta), they are given by:

**zernikeR(n, m, r)\*exp(it)**.
